VER	Verified Emissions Reduction

*"Since 1950, East Kalimantan has reduced its forest cover by 35 percent (6.9 million hectares)."* 

## Foreword

Indonesia understands the grave threat that climate change poses to our nation and the world. Under the leadership of President Susilo Bambang Yudhoyono, Indonesia has taken action and created new momentum in the global negotiations for serious action to combat climate change. By hosting the COP 13 in Bali in 2007, voluntarily announcing a commitment to reduce its carbon emissions by 26 percent by 2020 and by signing an agreement with Norway in 2010 for pay-forperformance emissions reductions Indonesia has taken an crucial international leadership role.

Conventional thinking posits that reducing carbon emissions must come at the expense of economic growth, with environmental financing and international assistance providing a form of welfare payment to compensate local communities for these losses. This need not be the case. In fact, the scheme to reduce emissions from deforestation and forest degradation (REDD) that was introduced at the Bali Climate Change Conference in 2007 can help move Indonesia onto a more environmentally sustainable development growth path – a path that does not sacrifice economic growth.

For a democratic and decentralized country such as Indonesia, the provincial and district-level governments are at the heart of this challenge. The Provincial Government of East Kalimantan and the National Council on Climate Change (Dewan Nasional Perubahan Iklim, DNPI) have launched this Environmentally Sustainable Development Strategy (Strategi Pembanguan Ramah Lingkuan) to chart a new development plan for the province. We intend to pioneer a new development pathway that reconciles economic growth with significant reductions of greenhouse gas emissions in line with the President's target of 7% annual economic growth and 26% reduction in emissions.

This report analyses and evaluates the potential for environmentally sustainable development in East Kalimantan. It first outlines a fact-based assessment of current and likely future GHG emissions for the province and then considers the potential actions to reduce emissions, the relative volume of each of these reduction measures, and an indication of costs (or gains) per measure. The report then identifies how the province can move to higher value-added activities and new green sectors so that its future growth leaves a smaller carbon footprint. Recognizing that a degree of climate change is already locked in by recent CO2e rises, and despite current global action, the strategy also explores adaptation measures, which aim to make the province more resilient to climate change.

We hope that East Kalimantan's success will make it a showcase of how to combine carbon abatement with economic growth not just in Indonesia, but also globally. We hope to inspire others to recognize the potential for environmentally sustainable development. Neither DNPI nor the Government of East Kalimantan underestimates the challenges in making the shift to such a new model of development. As in other parts of Indonesia, the underlying drivers of emissions in East Kalimantan are strong, entrenched, often based on highly profitable activities, and abetted by weaknesses in the country's still-developing institutions. Yet the journey must begin, step by step. President Yudhoyono has taken the first steps with his leadership and commitments. The Government of East Kalimantan, under my leadership has taken the next step committing East Kalimantan to a more sustainable future. This strategy marks another step forward.

19 May, 2011

Dr. H. Awang Fareok Ishak Governor East Kalimantan

## Acknowledgements

The DNPI and the Government of East Kalimantan would like to express their appreciation to the Climate Land Use Alliance and the Norwegian Government for partially funding this effort to develop an environmentally sustainable development strategy for the Province of East Kalimantan.

The DNPI and the Government of East Kalimantan would like to acknowledge Daemeter Consulting, McKinsey & Company, Mulawarman University, The Nature Conservancy (TNC), and The World Wildlife Fund (WWF) for their analytical support in connection with this study. The DNPI and the Government of East Kalimantan would also like to thank the several hundred government, private company, and NGO personnel who made important contributions to this work in various workshops and meetings. While the data and input came from many stakeholders and information sources, the conclusions and results set forth in this report are exclusively those of the DNPI and the Government of East Kalimantan. "Our vision of a Green East Kalimantan also involves developing new, environmentally sustainable economic sectors that are also equitable and meet our belief in "developing East Kalimantan for all."

## Executive summary

East Kalimantan has an ambitious goal to become a Green Province. This goal includes contributing to a 26 percent reduction in CO2e emissions by 2020 as part of Indonesia's national commitment. Our vision of a Green East Kalimantan also involves developing new, environmentally sustainable economic sectors that are also equitable and meet our belief in "developing East Kalimantan for all."

The document also sets out a comprehensive series of initiatives aimed at climate-compatible economic development. We consider the measures we need to take to protect our people from the impact of climate change. Together, abatement measures, adaptation measures and development opportunities create the framework for our province's climate compatible development strategy.

#### **EMISSION ABATEMENT**

Five broad initiatives account for 75 percent of all of the CO2e reduction opportunities in the province. And while they demand different approaches, these efforts all share something in common: increasing the efficiency of land use.

1. The single most important measure we can take to cut emissions is to enforce a zero **burning policy.** This effort achieves the greatest abatement at the lowest cost. By prohibiting the use of fire as a tool to clear land, by enforcing this prohibition, and by creating a system of early warning and fire brigades, we can prevent damaging forest and peatland fires. This can reduce emissions in East Kalimantan by as much as 47 MtCO2e by 2030 at a cost of USD 0.40 per ton.

Since the devastation of the 1980s and late 1990s, we've learned much about the damage caused by these fires, and equally, about the practical difficulties of preventing them. Enforcement remains the biggest challenge. We've also learned that the economic pressures that drive farmers, planters and miners to use fire as a tool are felt most keenly by smallholders, and so our efforts must give them clear incentives and tools to use alternative methods of land clearing.

2. Reduced impact logging is the second largest abatement opportunity overall, with the potential to prevent 34 MtCO2e of emissions at an implementation cost of USD 1.10 per ton. Reduced impact logging will require a relatively high investment of more than USD 100 per hectare and could be even higher if substantial investments in road construction are required. While the forestry sector economic contribution is less to East Kalimantan than it has been in the past, it still remains important for many of our most rural communities. Poor logging practices, often carried out in violation of existing laws and regulations, mean that for every ton of carbon harvested into saleable timber, as many as another five tons are emitted from timber which is damaged, and left to rot or burn as waste.

We need to improve harvesting planning, and extracting practices. We need to change the behavior of our loggers, and this will require a major investment in forestry management units across the province, and as well as investment in road and skidding infrastructure, both from government and from forestry companies. Last but not least, investments in skidding technology and the training of forest workers are also required. These efforts will require a relatively high investment of USD 150 per hectare, but a truly sustainable forestry industry could be an important source of livelihoods for us for many years to come.

- 3. Reforestation and rehabilitation of forests that have been partially degraded will restore ecosystem services and also absorb carbon, providing a reduction of emissions of 12 MtCO2e at a cost of USD 2.60 per ton. The forest estate under the administration of the national Ministry of Forestry includes some 1.5 million ha of "slightly critical land" (agak kritis) that has been degraded by unsustainable logging practices. These forests can be restored, and serve eventually as carbon sinks, but in order to do so they must be set aside for conservation.
- 4. Rehabilitation and water management of previously opened peatlands offers the possibility of saving some 18 MtCO2e at an average cost of USD 0.50 per ton. Peat soils play a critical role in carbon emissions in our province, and once drained and degraded they may emit CO2 for many years. We are coming to understand more and more of the role of peat in emissions is relatively new, but betterhow management of the water table of our peatlands can cut emissions dramatically and still allow economic use of lands that which are already cleared. On top of high carbon emissions there are additional arguments against the clearing of peat forests, such as flood prevention and protecting high biodiversity, and these should also be taken into account when granting permits for alternative land uses.
- 5. The use of degraded land *(lahan kritis)* for future expansion of oil palm plantations, timber plantations, and agriculture will allow us to grow these critical industries while providing a reduction of emissions of 24 MtCO2e at a cost of USD 5.50 per ton. As many 1.4 million hectares in the province are categorized as very critical or critical lands. The terms cover different categories of land, including those with negligible or little tree cover or even mostly covered by unproductive *alang-alang* grasslands. About one third of these degraded lands are found in contiguous fields of 500 ha and larger. Using these areas for plantations of oil palm or pulpwood would avoid deforestation of equally sized forests.

One first step to enable the expansion of plantation on degraded land is the development of a provincial degraded land database, which looks at soils, forest cover, existing usage and land tenure, as well as other dimensions of economic potential. Degraded lands need to be specifically identified in the spatial planning process, and should be prioritized over forested areas for plantation location permits. Subsidies for the use of degraded land and/or high carbon taxes on forested land might also be necessary to encourage the private sector to use degraded areas. It might also be necessary to compensate oil palm concessionaires to shift from forested land to degraded land.

Considering all the practical constraints, the timely use of degraded lands could save some 500,000 hectares of forests in the province. More use of degraded land could be achieved relatively quickly if the issuing of new concessions for oil palm cultivation were simultaneously put on hold, as indeed has been announced by the President as part of the Norway-Indonesia REDD+ Partnership.

#### SUSTAINABLE DEVELOPMENT EFFORTS

Hand in hand with our efforts to abate emissions, there are a number of complementary growth initiatives that we should pursue urgently, as part of a sustainable economic development effort. The top five such efforts could increase GDP by IDR 68 trillion in 2030, and so increase our growth from 3 percent per year to 5 percent without increasing emissions. The emphasis here is on capturing more of the value-added from the processing of our natural resources.

- 1. **The development of coal-bed methane** would bring important new stocks of natural gas online, while mitigating the environmental harm of methane emissions from existing coal mines. Use of CBM will ensure that our existing LNG and natural gas network and industry in the province is fully utilized as production declines in our offshore fields.
- 2. **Develop integrated pulp and paper mills.** Making use of timber now discarded as waste, boosting productivity on existing timber plantations and bringing idle timber plantations into production would increase the supply of timber from sustainable resources to the extent that the province could develop two integrated pulp and paper mills, with a total capacity of 2.6 million tons. Improvements in land management and a sequenced financing approach will mitigate the risk that building mills creates demand for unsustainable timber harvesting.
- 3. Improved management of timber plantations could yield IDR 4.9 trillion in additional GDP. Some 600,000 hectares of lands cleared for timber plantations, but currently sitting idle can be brought into production. This wastage of land is a legacy of poor past practices by the pulp and paper industry. Still, looking forward, pulpwood production on already cleared land is sustainable, especially in synergy with the other initiatives set out here. Plantations with short planting cycles are carbon neutral at best, but they can provide livelihoods and form the foundation for higher-value-added activities. In addition, we need to improve the productivity of our existing timber plantations to the levels reached in Sumatran plantations.
- 4. Accelerating oil and gas exploration is also important for slowing the decline in the oil and gas sector, which is still the largest in the economy. Our existing fields are mature and face declining production. There are still significant estimated potential gas resources in the province, yet exploration activity has decreased as with all of Indonesia due to uncertainty in regulations. We aim to encourage more petroleum exploration by working with BP MIGAS to be more investor friendly and by directly facilitating local licenses and security
- 5. **Increasing productivity of our agriculture sector is also important.** Yields from nonpalm oil agriculture are some 25 percent below national norms. Incentives to farmers, better infrastructure, development of innovative nucleus-plasma schemes to increase the synergies between plantation agriculture and smallholders and more delivery of agricultural extension services all could help increase our productivity. Simply hitting the national average would add some IDR 2.9 trillion to provincial GDP by 2030, while benefitting rural populations

#### **ENABLERS**

There are three levels of action required from government to capture the abatement opportunities and enable the economic activities set out in brief above, and in more detail in the pages that follow. These form perhaps the most critical sets of actions required, because without the right governance of climate change mitigation and sustainable development, we will not succeed.

**First, much of what needs to be done is simply to better enforce existing rules.** For more than ten years we've suffered the ill effects of peatland and forest fires, and struggled to combat them. Our forestry and mining regulations embody much wisdom and best practice. The challenge is clearly in enforcing the rules that we have on the books, and in clarifying and settling whatever ambiguities or overlaps may constrain better regulation. While we can expect to attract added support from outside, given the importance of good governance of our forests to the global carbon emissions picture, which will be useful, but the success factors are in our control.

Secondly, there are clear opportunities to adjust and reform our regulatory and enforcement regime, to better fit the realities of today's economy and the challenges of sustainable development. Elements of existing regulations on forestry, to choose one example, do not incentivize our loggers to follow sustainable practices. Government regulations on energy investments need to be updated to better suit the requirements of the coal-bed methane industry. This report recommends a number of incremental reform and adjustments, either in our provincial systems, or in national or local ones.

Much of the effort required here involves clarifying and rationalizing our spatial management system. Lands must be managed based on environmental and economic factors, not bureaucratic classifications that poorly reflect ground-truth. Creation of a new land-management system cannot be carried out by the Provincial government alone, or any single Ministry, but it is at the heart of our goal of improving the productivity of our lands. Sometimes lack of transparency in land ownership and licensing is a simple reflection of the complexity of overlapping claims, including traditional ones of course. So side-by-side with any attempt to rationalize our maps and geographic databases, we must institute a process of settling claims that is highly sensitive, highly responsive and involving of local communities, and yet decisive and speedy.

And lastly, in some cases we do need to build completely new systems to tackle climate change challenges. For example, we need to begin to build a system and method for measuring changes in emissions in the province. A good MRV system for measuring emissions changes is an essential building block to a scalable REDD or REDD+ regime. While REDD payments for avoiding deforestation are not among the most important emissions abatment measures on our agenda, they are certainly important, and have the potential to most directly channel funds to those who protect forests, foregoing the benefits of exploiting them. This is a new function that our government will have to create, leveraging the good work done by other governments, development partners and non-governmental organizations around the world.

Our analysis tells us that we can achieve growth and cut our carbon emissions. Our experience warns us that this is difficult, but also gives us faith that much can be achieved, as we look at our province's record of development over the last decades. Achieving this change will also require significant financial resources; we estimate reducing our emissions with these initiatives will cost USD 2.00 - 3.10 per ton CO2e abated. These costs will ramp up over time, from USD 20-30 million in 2012 to USD 370-570 million in 2030.

East Kalimantan is a highly diverse society, as befits the richness and variety of our natural environment, from our forests and mountains to our seashores along the trading routes of Southeast Asia. To develop, we must unleash the drive and creativity of all members of our society. Environmentally sustainable development means that this creativity and drive will be built on a foundation of respect for our god-given natural heritage.

### Executive summary | 17

"...forests provide vital ecological and environmental services such as watershed protection, biodiversity, habitat for countless species."

## Kaltim Green Program

The Government of East Kalimantan has created the Kaltim Green program, the province's framework for sustainable development and reduction of greenhouse gas emissions.

The program was announced at the provincial event "Regional Initiatives in Anticipation of Global Warming and Climate Change Mitigation" (*"Inisiatif Daerah Dalam Mengantisipasi Pemanasan Global and Mitigasi Perubahan Iklim"*) held on 1 December 2009 in Balikpapan.

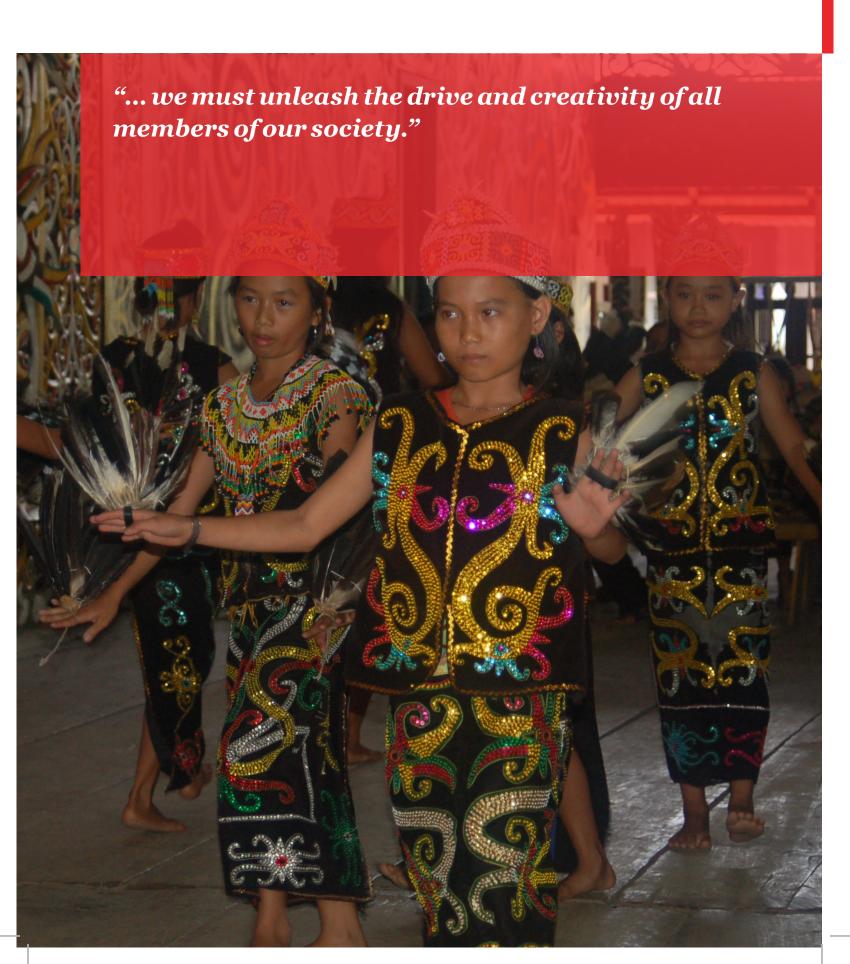

The Kaltim Green Program has four objectives:

- Improve the overall quality of life of people of East Kalimantan, balancing economic, social, cultural, and environmental aspects
- Reduce the threat of ecological and climate change threats such as flooding, landslides, droughts, forest fires across East Kalimantan
- Reduce pollution and degradation of the quality of terrestrial ecosystems, water, and air in East Kalimantan
- Increase the knowledge and awareness among the institutions and people of East Kalimantan that the conservation of natural resources is important and that resources must be used wisely

The Kaltim Green Declaration, agreed to by the Provincial and District governments across East Kalimantan, acknowledges the urgency of action to reduce greenhouse gas emissions and includes five commitments:

- a) Carry out low carbon emission development;
- b) Integrate sustainable development targets for the region;
- c) Analyze and reform current development policy accordingly;
- d) Promote the local research required to address climate change issues by supporting the province's network of universities and colleges (especially in forestry); and
- e) Support mitigation efforts in cooperation with international institutions.

This Environmentally Sustainable Development Strategy has been created as part of the Kaltim Green Program and is a plan of action to achieve this vision.

# 1. The context for East Kalimantan's development

#### East Kalimantan has achieved an impressive record of economic development for its

**people.** East Kalimantan has the second highest GDP per capita of any province in Indonesia and its economy reached a sizeable IDR 103 trillion' in 2008. Since 2000, the province's poverty rate has fallen by 10 percent per annum while per capita consumption has risen by 12 percent p.a. This reflects the long-term development path of the province; since the 1970s East Kalimantan has increased the life expectancy of its people from 56 to 71 years, reduced illiteracy from 50 percent to 4 percent, and has increased the number of community health centers from a mere 50 to over 850.

This development has been largely driven by the exploitation of the province's abundant natural resources. The pumping, cutting, mining, and processing of East Kalimantan's oil, gas, timber, coal, and other mineral deposits accounted for more than 80 percent of GDP in the early 1980s and two-thirds of GDP in 2008. Oil has been a mainstay of East Kalimantan's economy since the 1880s when Indonesia became the third country to find and produce oil commercially. The discoveries of large oil and gas deposits in the 1960s and 1970s transformed the province; it has Indonesia's largest liquefied natural gas (LNG) plant in Bontang and second largest refinery in Balikpapan. Since 1950, East Kalimantan has reduced its forest cover by 35 percent (6.8 million hectares). East Kalimantan has 25 percent of all coal deposits in Indonesia as well as an estimated 60 million tons of unexploited gold deposits.

Economic development remains an imperative for the almost 260,000 people in East Kalimantan still living below the poverty line. While the province has made impressive gains in living standards, nine percent of the population still earns less than IDR 225,000 per month, the provincial poverty level. Decentralization has increased the accountability and pressure on district heads (bupatis) and the governor to extend economic opportunities and increase incomes. Although the province's working population has actually shrunk since 2000, creating new jobs remains a political imperative as the unemployment level stood at 11 percent in 2008. Incomes, likewise, have much room to rise; the average citizen of East Kalimantan spends just IDR 420,000 per month on housing, food, and basic necessities.

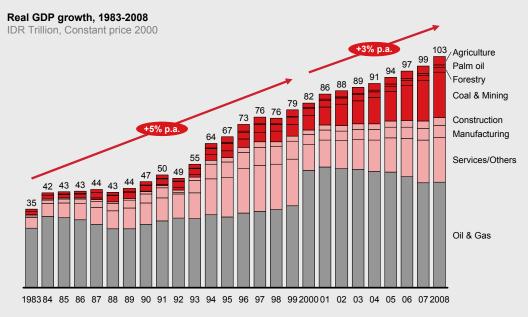

Under a business-as-usual growth scenario, East Kalimantan's economy will grow only at a moderate 3 percent p.a., as new growth from coal mining, palm oil, and services will be partially offset by the continued decline of the oil and gas sector (EXHIBIT 1). The GDP contribution from oil and gas has decreased by one percent per annum over the last few years, and is expected to continue to fall as production rates decline in the East Kalimantan's mature fields. As oil and gas currently make up almost 50 percent of the economy, this decline acts as a brake on the overall economy's growth. Going forward, the provincial economy's growth will be increasingly influenced by sectors such as coal mining, palm oil, and services.

<sup>1</sup> Real GDP in constant 2000 prices. Unless otherwise noted, all GDP figures in this report are in real (constant 2000) prices and not nominal prices.

#### 22 | The context for East Kalimantan's development

#### Exhibit 1

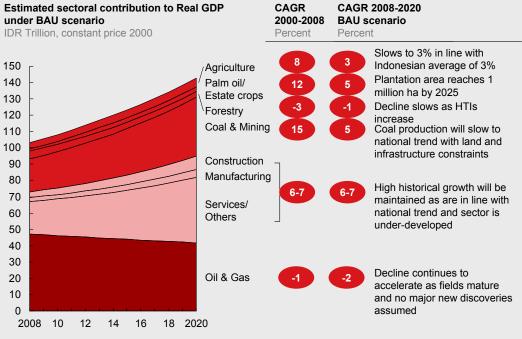

#### East Kalimantan's economy has been driven by the oil and gas sector, however this is in decline while coal, palm oil, and services are growing fast

SOURCE: BPS

#### Exhibit 2

#### East Kalimantan's economy will shift toward coal, services, and palm oil

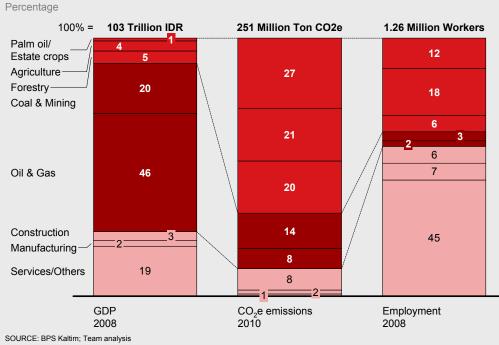

SOURCE: Team analysis

This resource development pathway has also led to sizeable CO2 emissions, with 250 MtCO2 expected to be emitted in 2010 alone, making East Kalimantan the third largest emitter among Indonesia provinces. Sectors accounting for just one-tenth of the province's GDP are responsible for 68 percent of all emissions; agriculture, forestry, and palm oil plantations create the majority of East Kalimantan's emissions via deforestation, forest degradation, fires, and the draining of carbon-rich peatlands. East Kalimantan stores (or sequesters) a remarkable 4.2 billion tons of carbon (15.4 billion tons of CO2 equivalent) in its forest and peatlands; thus changes in the use of these lands risks creating emissions far in excess of the sectors typically thought of as high emitters, such as manufacturing, and oil and gas production and refining.

Emissions will continue to grow under the business-as-usual scenario, reaching an estimated 303 MtCO2 in 2020 and 331 MtCO2 in 2030, a 32 percent increase in total. It is true that as the economy develops and moves to higher value added sectors, its carbon intensity (CO2 output for a given amount of GDP) will decrease. But it is absolute emissions that affect climate change and these will rise as the palm oil, agriculture, forestry, and coal mining sectors increase their use of forested land. New power generation and increased transportation will be significant in terms of emissions growth, but still small when compared to the total emissions.

Addressing this development trajectory is complicated by the fact that East Kalimantan's 14 districts have significantly different economic and emissions profiles, with three districts accounting for 55 percent of all provincial CO2 emissions. Kutai Kertanegara, Kutai Barat and Nunukan make up 55 percent of the provincial emissions, largely due to the draining of and fires on the approximately 800,000 ha of peatlands in these districts as well as the combined 60,000 ha of annual deforestation there. The cities of Tarakan, Bontang, Samarinda, and Balikpapan emit less than 10 percent of total emissions, but their economies are guite different with Bontang and Balikpapan as major oil and gas centers, and Samarinda and Tarakan dominated by the service sector (including public administration for Samarinda, the capital).

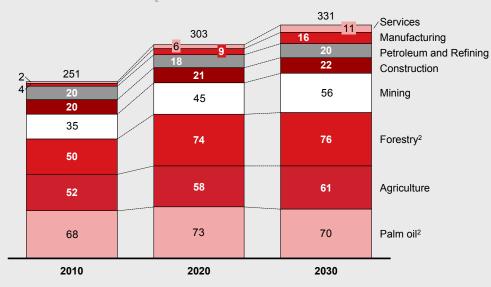

### Five sectors are critical for GDP and CO<sub>2</sub>e emissions: Agriculture, palm oil, forestry, coal, and oil & gas

Exhibit 3

#### Exhibit 4

## CO2 emissions are expected to grow from 251 to 331 $\rm GtCO_2e$ between 2010 and 2030

Projected emissions<sup>1</sup>, Million tons CO<sub>2</sub>e

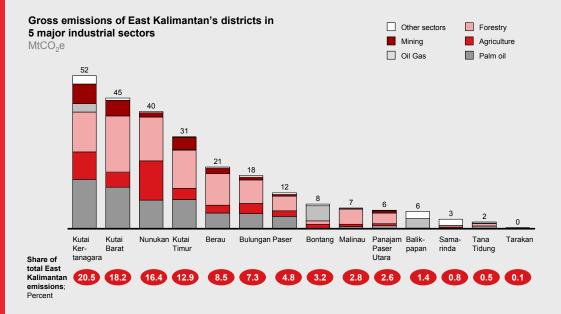

1 Includes only direct emissions from each sector

2 Emissions from Forestry and palm oil are based on a net emission approach i.e., including absorption

SOURCE: Indonesia GHG Abatement Cost Curve

#### Exhibit 5

## Emissions are not evenly distributed with the three largest districts contributing more than 50% of all emissions

SOURCE: Kaltim Green, Wetlands International, East Kalimantan Statistics 2009, DNPI - Indonesia GHG Abatement Cost Curve

Both Berau and Malinau are large, still heavily forested districts. But Malinau is part of the Heart of Borneo area with protected forests, and thus has one third of the emissions of Berau despite being 30 percent larger in size. Likewise, forestry and non-timber forest products make up 40 percent of Malinau's GDP, whereas the largest sector in Berau is coal and mining at 40 percent of its GDP. Thus, a one-size-fits-all policy for low-carbon growth for the province would be impractical, given the different economic and emission realities facing East Kalimantan's districts.

# 2. East Kalimantan's environmentally sustainable development strategy

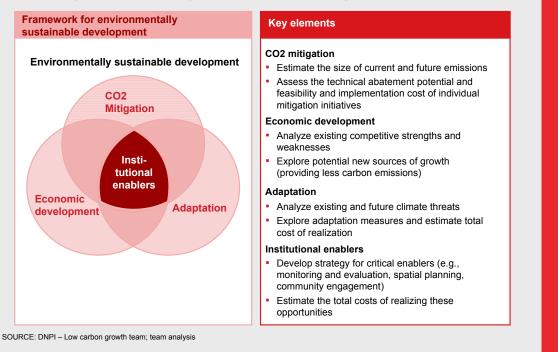

#### East Kalimantan is committed to moving onto a climate-compatible development

**pathway.** In a developing economy like East Kalimantan, the people will not choose to reduce CO2 emissions if to do so means retarding economic growth. This strategy does not require that choice. A core principle of this development strategy is that economic development and CO2 mitigation can be mutually reinforcing. East Kalimantan's low carbon growth strategy reconciles growth with climate change mitigation by focusing on: 1) reducing the carbon footprint of its current economic sectors, 2) moving to higher value-added activities and new low-carbon activities, and 3) acting to make the economy and infrastructure resilient to climate change.

### Achieving truly climate-compatible development will require substantial changes to East Kalimantan's economic structure, land-use planning, and government policy.

will also require a new mindset focused on long-term, environmentally-sustainable development taking hold within the government, the business community, and the non-profit sector. Finally, these changes will require additional financing. As above, a principal goal of the low carbon

#### Environmentally sustainable development is a holistic approach where economic growth, CO2 mitigation, and adaptation go hand in hand

#### Exhibit 6

growth strategy is to ensure that the people of East Kalimantan do not achieve reduced emissions at the cost of reduced growth. Additional financing will needed to underwrite the considerable investments associated with the transition to a climate-compatible development path. Some of that financing will likely be provided by the domestic government, some by international donor agencies, and some directly by the private sector as companies see the potential to generate positive returns.

**East Kalimantan can reduce the carbon footprint of its current economy by 60 percent from the business-as-usual trajectory by 2030.** This reduction comes mainly from the five priority sectors of palm oil, forestry, agriculture, coal mining, and oil and gas. A total of 22 initiatives in these sectors could reduce the province's emissions by 184 MtCO2 (an additional reduction of 13.2 MtCO2e could be achieved by activities focusing on other sectors, for example construction) at an average cost of USD 2.0 to 3.1 per tCO2e abated. This represents a reduction of 60 percent from the level of emissions expected in the business-as-usual scenario in 2030.

**Five abatement initiatives account for 75 percent of all the CO2 reduction potential in East Kalimantan. All five focus on increasing land-use efficiency.** The maximum reduction from these initiatives would be 135 MtCO2 by 2030, although a number of challenges would need to be overcome to reach the full reduction. All of the abatement initiatives described in Table 1 are discussed in more detail in Chapter 3, Sector Strategies.

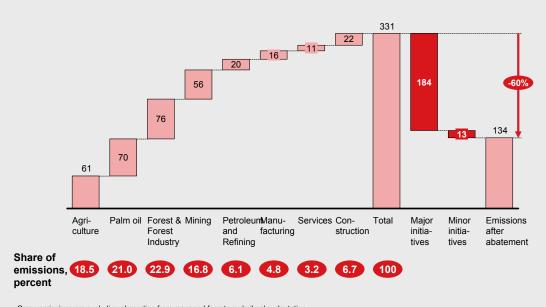

East Kalimantan can increase its GDP growth from a business-as-usual rate of 3 percent p.a. to 5 percent p.a. without increasing emissions by moving to higher value-added activities and promoting less carbon-intensive sectors. East Kalimantan has a relatively diverse economy, especially when compared to provinces outside the heavily-populated Sumatra-Java-Bali chain. Yet, with a population of only 2 million, East Kalimantan has only a small domestic market. Much of its abundant resources are exported in raw form to Java, Sumatra and overseas where they are turned into higher-value added goods (e.g., raw logs to Sumatran mills and Javanese furniture manufacturers). East Kalimantan has an opportunity to capture more downstream processing and thus increase the GDP contribution that the province gains from its natural resources.

The top five economic initiatives could increase GDP by IDR 50 trillion in 2030, equivalent to IDR 9 million per person (Table 2). These initiatives include developing a new resource (coalbed methane), improving productivity of underutilized sectors (timber plantations and agriculture in particular), and developing downstream activities such as a pulp and paper mill and CPO refinery. Each initiative is described in more detail in the relevant sector strategy.

This increased growth will require safeguards to ensure that it does not encourage other sources of emissions. Increasing the productivity of HTI and palm oil concessions, for example, could make them more attractive for investors and thus encourage the development of new concessions in forested lands if measures, such as REDD, are not in place to prevent this. Similarly, developing additional pulp and paper processing capacity without first ensuring a sustainable supply of acacia could simply accelerate deforestation by increasing demand for current unsustainable logged timber. Financial safeguards, proper sequencing, and thoughtful spatial planning will all be needed to ensure the shift to environmentally sustainable GDP growth.

While GDP is an important and visible indicator of development, it is not the only metric that is important to the people of East Kalimantan. Our official slogan of "Develop East Kalimantan for all" recognizes that too much of the province's natural resource extraction has benefited a few companies and individuals as opposed to creating jobs and income for the majority. Creating jobs, improving rural incomes, and reducing inequality are also vital parts of our sustainable development strategy. Beyond reducing CO2e emissions, we have important environmental goals to reduce pollution, maintain natural resources, protect fisheries, protect water quality and retain watersheds to reducing flooding. East Kalimantan is home to important biodiversity which we want to protect, represented most notably by a number of rare and beautiful

## In the BAU scenario, $CO_2e$ emissions would reach 331 Mt by 2030, however pursuing a sustainable growth path can reduce this by 60 percent

Gross emissions are excluding absorption from managed forests and oil palm plantation SOURCE: team analysis

## East Kalimantan has the potential to reduce $CO_2$ emissions by up to 184 MtCO<sub>2</sub>e by 2030 at an average cost of USD 2.00 – 3.10 per ton $CO2_e$ abated

1 Societal perspective implies utilizing a 4% discount rate

## Shifting into higher value add activities and low carbon sectors could boost East Kalimantan's real GDP growth from 3% to 5%

animals and plants, such as the orangutan, clouded leopard, and river dolphins. Finally, East Kalimantan wants to be known as a green province and be an important contributor to Indonesia's effort to be a global leader in addressing climate change.

**REDD (Reduced Emissions from Deforestation and Degradation) is a new framework that** *can both help reduce emissions and increase GDP.* REDD+ is an international mechanism to mitigate global climate change by creating payments to protect forests and peatlands that would otherwise be converted from their natural state, for example, to be used as plantations. In fact, the abatement initiatives identified above can be considered to be part of a REDD+ strategy; reducing forest degradation through better logging techniques, ending the use of fire for land clearing, rehabilitating degraded peatlands, reforesting lands, and using degraded lands rather than forested lands for agriculture. REDD+ could be a powerful integrating framework for these initiatives. For example, after a concession is moved from forested land to degraded land, REDD payments could be used to ensure local communities and companies then protect the forested land. Otherwise, the forested land would be at risk of having a new, different concession issued for it in the future unless the land was re-zoned as protected land.

Concession buyout schemes, in which concessions are purchased from concession license holders to prevent forest clearing, should be a last resort as they could be quite costly. If an acacia plantation concession on forested land could not be moved to degraded land or reduced in size via improved yields, then the only option to avoid deforestation would be to buy out the concession in full. Payment for buyout schemes are still being worked out. For those cases where only past expenses or outlays are compensated, the cost of these schemes could be high, but not unreasonably so on a cost-per-abated-ton basis. However, if it were required to compensate concession holders and local communities for the complete loss of future revenue, then costs would become prohibitively high. Concession buyouts for palm oil and acacia concessions could

TOP 5 ABATEMENT INITIATIVES									
Top 5 abatement initiatives	Description	Abatement MtCO2, 2030	Cost USD per tCO2						
Zero burning policy	Prohibiting fire as a tool for land preparation, establishing fire brigades, and ensuring strong enforcement and large penalties for rule violations can reduce emissions from peat and forest fires	47	0.35 to 1.35						
Reduced impact logging	Reduced impact logging, e. g., skidding tracks, winches, and harvest planning, can remove commercial timber with less destruction of non-commercial biomass. This lowers emissions from deforestation significantly. Forest management units are required to supervise logging, with about one forest employee overseeing	34	0.40 to 1.50						
	15,000 ha of a natural timber concession								
Use of degraded land	Use of degraded land (lahan kritis) for future expansion of oil palm plantations, timber plantations and agriculture will allow expansion with lower emissions by avoiding deforestation for new concessions	24	2.6 to 9.8						
Rehabilitate opened peatland	Reducing emissions from peat decomposition of agricultural areas can be achieved by adjusting and maintaining the water table at appropriate levels via dam systems and applying best practices in rice cultivation	18	0.20 to 0.70						
Reforestation	Rehabilitating land that has been partially degraded and reforesting will restore ecosystem services and also absorb carbon	12	2.0 to 3.1						

### **TOP 5 GDP INITIATIVES**

Top 5 GDP initiatives	Description	GDP, Tr. IDR 2030 (percent of 2030 BAU GDP)
Develop and utilize coal-bed methane	Support development of exploration and production of the coal- bed methane reserves in East Kalimantan and feed into Bontang LNG, domestic gas network or additional downstream facilities.	27.9 (10%)
Build a 2.6 million ton pulp and paper mill	Develop two integrated pulp and paper mills with a capacity of 2.6 million ton.	10.7 (5%)
Improved management of timber plantations	Bring over 600,000 ha of currently inactive timber concessions into production. Incentivize investment in existing timber plantations to improve yields to the levels achieved in the best of Sumatran plantations	4.9 (2%)
Accelerate oil and gas exploration	Encourage more petroleum exploration by lobbying industry regulator to be more investor friendly and by facilitating local licenses and security	4.71 (2%)
Increase productivity of agriculture	Subsidize nucleus farmers and use extension services to improve yields by 20 percent to reach Indonesian averages	3.20 (1%)

### Table 1

Table 2

cost as much as USD 26 per t CO2e and USD 12 per t CO2e respectively, using a full opportunity cost methodology.

REDD+ is still in development, and the laws governing and allowing full REDD+ projects are still being drafted. Yet, donor countries attending the UNFCCC summit in Copenhagen in December 2009 committed USD 3.5 billion to jumpstart REDD+ schemes, which underlines the importance of this abatement option. REDD+ could potentially provide significant funding for avoided deforestation projects. However, funding is only likely to materialize at scale when more developed countries establish emissions trading systems (also known as cap-and-trade systems) and the private sector becomes the principal source of REDD financing.

East Kalimantan's environmentally sustainable development strategy is connected into Indonesia's climate change strategy at a national level. President's Yudhoyono's pledge to reduce Indonesia's total emissions by 26 percent against a business-as-usual trajectory by 2020 will have profound implications for businesses and economic planners across the country, and nowhere more so than in the high-emitting provinces such as East Kalimantan. All provinces and districts will be required to submit plans for capturing reduction opportunities. The DNPI is trying to ensure that a common approach to environmentally sustainable development strategies is being followed in different provinces, so that the data and recommendations contained within them can be more easily incorporated into an overall national Low Carbon Growth Plan.

Summing up across all sectors and all initiatives, East Kalimantan has the potential to shift to a more climate-compatible development model, which could reduce emissions in the province by 60 percent and raise GDP growth from 3 to 5 percent per year by 2030. Turning these aspirations into targets and results will require significant investments in capacity-building, legal enforcement, technology and equipment, deeper engagement with forest-based communities, and improved spatial planning. Progress in these areas will set the pace of East

Each district will contribute differently to these goals according to their emissions profiles and potential. Individual district strategies are detailed in Chapter 4.

### 3. Sector strategies

East Kalimantan has significant opportunities to reduce its current emissions and increase its GDP. For East Kalimantan, it is important to look at sustainable development strategies for each major part of the economy and not just for the whole. This is partly because important stakeholders in the province are grouped into different economic sectors (e.g., palm oil companies versus coal mining companies) and partly because our government administration is organized by sector, such as estate crops and forestry, as opposed to physical drivers of emissions such as deforestation. Once each major economic sector has a sustainable development strategy we can engage stakeholders on implementation. We hope that by having initiatives that both reduce the carbon footprint from current activities and also increase GDP through higher value-add activities, the companies and people working in that sector will support sustainable development as they will directly experience the benefits.

This chapter reviews each of the sectors in order of their current business-as-usual situation, their abatement opportunities, pilot projects, potential GDP improvements, and required policies (or changes to policies) to enable the changes in each sector.

- Palm oil
- Forestry
- Agriculture
- Coal
- Oil and gas

### **PALM OIL SECTOR**

This document analyzes palm oil separately from all other agricultural crops, as the palm oil sector <sup>2</sup> is critically important for East Kalimantan's economic growth and is also central to its CO2e emissions profile and abatement opportunities.. Indonesia is the world's largest producer of palm oil, yet East Kalimantan has only recently begun its development of the sector. While palm oil accounts for less than 1 percent of GDP currently, palm oil concessions are expanding rapidly. Palm oil is important beyond its GDP contribution as it is one of the few highly profitable activities in rural areas, thus bringing needed jobs and income to rural people and offsetting rural-urban inequality.

While the oil palm plant is highly efficient compared with other oil crops such as rapeseed, and the actual process of planting, harvesting, and milling palm oil produces relatively few emissions, the sector's expansion into forest and peatlands is creating substantial emissions and has made the palm oil sector the largest emitter in the province. We have identified initiatives to reduce more than 60 percent of palm oil's business-as-usual emissions, through a more efficient use of our land base. Instead of area expansion into forested areas, economic development can be achieved by agricultural intensification, better use of degraded lands, and by moving down the value chain into palm oil refining. However, these changes require supporting policies, training, and financial resources.

<sup>2</sup> Palm oil describes the overall industry sector, while oil palm is used to describe upstream operations within the plantations, such as cultivation of Elaeis guineensis

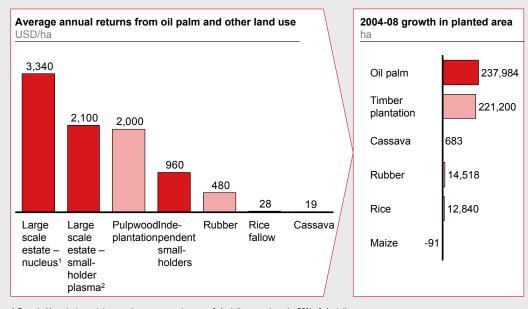

#### **Current Context**

**Palm oil is so profitable in Indonesia that it has earned the nickname of "liquid gold."** Oil palm is a highly profitable crop with annual returns<sup>3</sup> ranging from approximately USD 1,000 per ha p.a. in independent smallholder plantations to more than USD 3,000 per ha p.a. in large, privately-owned estates (EXHIBIT 11). These high returns have made oil palm the most important estate crop in East Kalimantan, with a GDP contribution of more than IDR 1 trillion in 2008. Palm oil is especially important for reducing poverty in rural areas of East Kalimantan; more than 40,000 smallholder farmers have planted some 85,000 hectares of oil palm. The sector's future looks bright as global demand is forecasted to increase, driven by growth in large export markets such as China and India.

Oil palm

#### Exhibit 11

## Significantly higher returns for oil palm than other crops has led to a rapid area expansion

1 Operated by private or state owned company; center core of plantation covering min. 80% of plantation area 2 Operated by smallholders, private, or state owned nucleus company is providing technical support SOURCE: APP, Grieg-Gran 2006, BPS Kalimantan Timur, Ministry of Forestry, team analysis

**Palm oil cultivation is expanding rapidly, growing by over 35,000 ha per year.** Currently approximately 465,000 ha<sup>4</sup> are planted with oil palm. Our official target, recorded in 2008, is to triple the sector's GDP contribution between 2008 and 2025,<sup>5</sup> which will require an additional 790,000 ha of plantings and investments into value-added CPO refining. Thus GDP from palm oil is expected to grow at an annual rate of 7.6 percent until 2020, reaching IDR 1.8 trillion in a business-as-usual scenario. Palm oil's growth is rapid in absolute terms but even more impressive when compared to other agricultural products, which are forecasted to grow moderately at 3 percent p.a., or to forestry, which is expected to continue its annual 3 percent decline. While palm oil's GDP may be overshadowed by the province's oil, gas, and coal sectors, it remains nonetheless important for its contributions to growth, jobs, and equality.

### Palm oil generates substantial emissions, 57 MtCO2e in 2010, and is expected to increase to 67 MtCO2e in 2030 due to continued rapid expansion of plantations.

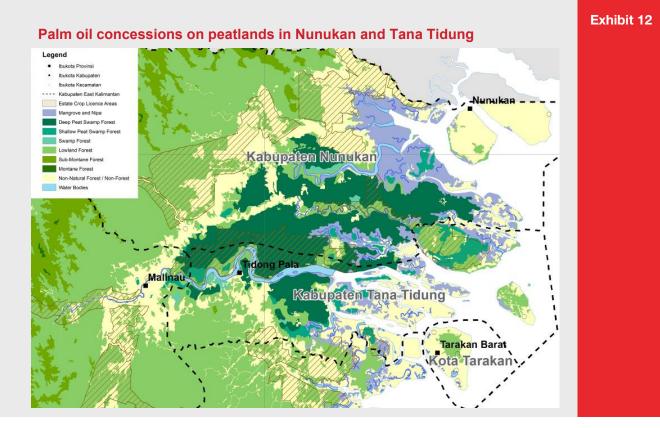

<sup>3</sup> At average crude palm oil (CPO) price of USD 700 per ton

<sup>4</sup> Dinas Perkebunan East Kalimantan

<sup>5</sup> Bappeda East Kalimantan

The sector's 57 MtCO2e of net emissions in 2010 make it the province's largest source of greenhouse gas emissions (GHG). Oil palm plantations require large tracks of land; in East Kalimantan this land has largely come from its forests and peatland areas as they provide some additional timber revenue but more importantly offer fewer land-tenure complications. Communicating, negotiating, and accommodating communities on land for palm oil concessions is a long and sometimes costly process. To the contrary, there is far fewer migration into intact forests and peatlands, and thus fewer land rights challenges. Consequently, palm oil cultivators say that the fastest route to an operating palm oil plantation is get a license to clear forested land. But it is precisely this expansion into forest and peatlands that results in the sector's very high emissions.

The majority of palm oil's emissions come from plantations opened on peatland. Peatlands have acidic water-logged soils, which in a dry state are 60 percent carbon in the form of organic matter that has accumulated over thousands of years. When peat soils are drained for oil palm cultivation, they are aerated and begin to oxidize and decompose. The slow but steady decomposition of peatlands is estimated to result in emissions of 17 MtCO2e in 2030, while the more rapid oxidation of peat carbon through fires is estimated to account for 26 MtCO2e per year on average.

**The second major source of emissions related to the palm oil industry is deforestation that occurs during the conversion of forested areas into plantations.** As conversion of (at least partly) forested areas is expected to continue through 2030, annual emissions of 22.4

MtCO2e from deforestation will likewise remain. Large companies primarily use mechanical techniques for land clearing and land preparation; however, many smallholders still use slash and burn techniques, which lead to significant emissions as well.

### Palm oil concessions expanding on forest lands in Bulungan and Berau

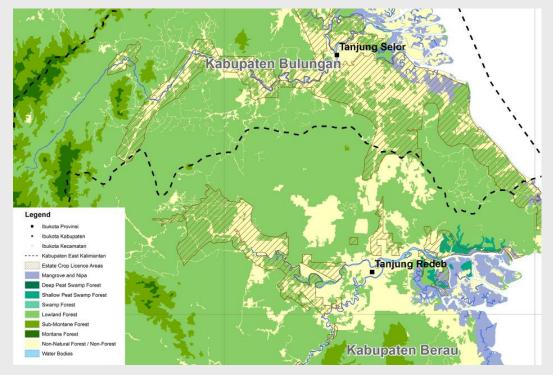

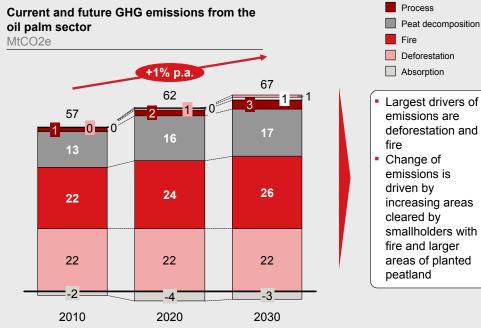

Exhibit 14

## GHG emissions from the oil palm sector are expected to increase in a business-as-usual scenario

Others

SOURCE: BPS Kaltim; WWF Indonesia, Dinas Kehutanan Kaltim, Departemen Kehutanan Indonesia, Dinas Perkebunan Kaltim, Team analysis

**Outside of the sector's need for land, palm oil's emissions are relatively minor.** Emissions from palm oil mill effluent (POME)<sup>6</sup> account for more than 1 MtCO2e currently. While comprising just one-fiftieth of emissions from land use, these emissions from the harvesting and milling processes are still significant. For example, POME emissions total half of the emissions from the province's entire transportation sector.

Total palm oil emissions are expected to increase at a rate of 1 percent annually and reach 67 MtCO2e in 2030 under business as usual (EXHIBIT 14) Emissions from oil palm-related deforestation are expected to remain constant, but overall emissions are expected to increase as more peatland is opened up for new oil palm plantations. New oil palm plantations on peatland in Nunukan, Kutai Kertanegara, and Kutai Barat districts (indicated by the location permits there) will result in significant additional ongoing emissions from peat decomposition. In addition, emissions from peat fires are expected to increase, as more peatland comes under cultivation and as smallholders continue to use fire as their main means for land preparation and fertilization. Annual emissions from peat fires will fluctuate, as the overall number of fires and the average area burnt during a fire event is correlated with annual rainfall, the groundwater table, and the duration of the dry season.

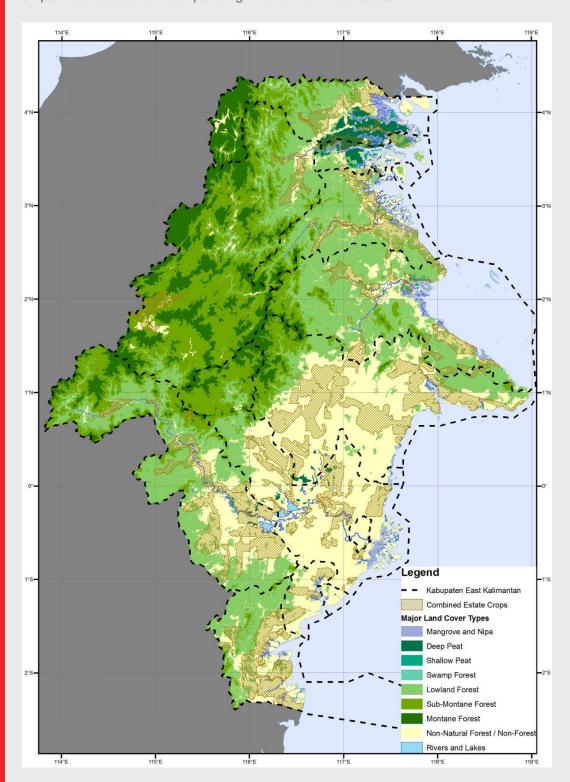

These estimates are based on the overall assumption that oil palm plantations will cover an area of approximately 1.25 million ha in 2030, which is based on projecting our official Propeda 2025 target to 2030. This plan indicates an additional expansion of 790,000 ha from the already planted 465,000 ha (EXHIBIT 15). However, districts have issued over 3.2 million ha of location permits, which would triple the above estimates if all were converted fully to oil palm. We have not used this as our baseline, however, as our Propeda plan has set a clear goal and districts do not have sole authority to issue palm oil concessions; the HGU licenses are issued by the provincial department of estate crops and the national land agency (BPN). In addition, an expansion to 3.2 million ha is unrealistic by 2030 as it would imply oil palm production would grow seven times-fold to 9.9 million tons which represents 50 percent of Indonesia's total CPO production at present. On a practical level, there is currently not enough infrastructure to support this development and this expansion would require 400,000 to 600,000 workers, which is approximately 30 percent of the current working age population.

#### **Abatement Potential**

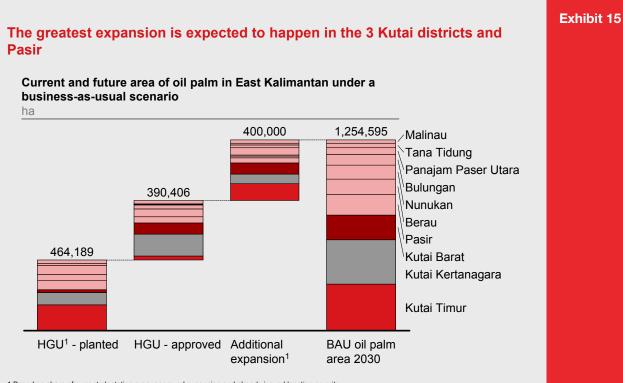

More than 43 MtCO2e of 67 MtCO2e of palm oil emissions could be abated annually in 2030 without reducing the GDP growth of the sector. This can be achieved by first setting a clear plan for palm oil in terms of CPO production as opposed to hectares planted and using productivity gains to replace some expansion of concessions. Next, we can reduce carbon loss from deforestation. Our first option is to use our existing degraded lands for new concessions and use land swaps for existing concessions with forest cover. Once those degraded lands are utilized, financial mechanisms (REDD payments) can be used to buy out remaining forest concessions. Finally, we would aim to minimize emissions from productive lands by instituting a zero burningpolicy and improving water management in opened peatlands. These five major initiatives, listed below in order of abatement potential, can result in a more efficient and productive use of the province's land (EXHIBIT 16).

The prevention of peat fires by the implementation of a strict and visibly enforced zero burning policy has the potential to reduce palm oil emissions by 15.6 MtCO2e at a relatively low cost of below USD 1 per avoided tCO2e. Capturing the emission reductions from this initiative will require providing technical equipment (and financial incentives) to enable smallholders to shift to manual land clearing, developing appropriate early-warning systems based on fire risk status, install satellite, and field-based fire detection systems, strengthening fire brigades, ensuring strong enforcement and severe penalties for rule violations, and last but not least, building public awareness of the economic and societal costs of forest fires in the province.

<sup>6</sup> Untreated palm oil mill effluent releases large amounts of methane as a result of anaerobic decomposition

Oil palm concessions are expanding into natural forest areas

1 Based on share of current plantation area, approved expansion and already issued location permits SOURCE: Dinas Perkebunan Kaltim, Expert interviews, team analysis

## Emission reduction activities in the oil palm sector should be focused around 5 major initiatives

	Description	Abatement <sup>1</sup>
Zero burning policy	<ul> <li>Implement zero burning policy along with strict and visible enforcement</li> <li>Increase fire fighting capacities within the province by hiring fire rangers and provision of appropriate technology</li> </ul>	15.6 Mt CO <sub>2</sub> e
Degraded land	<ul> <li>Promote use of degraded land (<i>lahan critis</i>) for future expansion oil palm</li> <li>Arrange land swaps of already granted concessions on forested land with equal sized plots of degraded land</li> </ul>	11.4 Mt CO <sub>2</sub> e
Peatland water management	<ul> <li>Implement water management within active oil palm concessions</li> <li>Protect remaining deep peatland in Nunukan, as the majority of undisturbed deep peatland is located there</li> </ul>	7.1 Mt CO <sub>2</sub> e
Yield improvements	<ul> <li>Initiate and implement extension services in cooperation with supportive private sector players to increase yield of oil palm with activities focusing on smallholder farmers</li> <li>Higher yields will help to reduce pressure on forest areas</li> </ul>	3.3 Mt CO <sub>2</sub> e
Concession buyouts	<ul> <li>Introduce a REDD payment scheme to compensate concession holders for forgone revenues for not starting an economic activity</li> <li>Apply REDD when the use of degraded land is no alternative</li> <li>For the biggest effect on emission abatement, REDD activities should focus on peatland or other areas with high carbon value</li> </ul>	3.2 Mt CO <sub>2</sub> e

1 Maximum technical annual abatement in 2030 2 Reduced emissions through avoided deforestation, assuming adequate funding from voluntary carbon markets or international bi or multilateral funding SOURCE: Team analysis

## Exhibit 16

The technical maximum potential for CO2e reduction through zero burning could be as high as 26 MtCO2e annually if all fires set by oil palm growers in East Kalimantan were suppressed. However, we recognize this would require large investments in infrastructure and fire prevention programs across a very large and difficult terrain. Thus, this strategy uses a more conservative abatement estimate of 15.6 MtCO2e, which could be achieved by focusing on the historical fire hot spots within the province.

Using existing degraded lands for the expansion of palm oil plantations could result in 11.4 MtCO2e of abatement annually by 2030. East Kalimantan has large areas of land that have been heavily degraded through previous deforestation, forest degradation, and the massive fires of the 1980s and 1990s. As many as 1.4 million ha are categorized as very critical (*sangat kritis*) and critical (*kritis*), with remaining tree cover of less than 10 percent and less than 30 percent respectively. Large areas of very critical and critical land are covered with *Imperata cylindrica (alang-alang)* and other weed species or bushes as their main vegetation with low carbon values. These degraded lands require roughly equal amounts of fertilizer (primarily rock phosphate) as forest lands and have approximately the same costs for development excluding any potential one-off revenues from selling cut timber on forested lands. Using degraded land for oil palm expansion will not only prevent emissions, it could even result in a net sequestration of carbon as long as the initial carbon levels are below 40 tCO2e per ha.

Only the larger plots of available degraded land are economically interesting for palm oil plantations investments from the private sector. About 40 percent of the land categorized as very critical and critical (approximately 550,500 ha of the total 1.4 million ha) consists of contiguous fields of 500 ha and larger. The rule-of-thumb estimate for the area needed for an economically attractive palm oil concession is 5,000 ha. We have focused on plots of degraded land of 500 ha or greater as we believe that they are typically found close to one another and can be consolidated with proper efforts. Thus, these areas could be used for oil palm cultivation and avoid deforestation of equally sized forests. To enable the use of degraded land, a degraded land database has to be developed that will identify the location, soil type, owner, and current land use. Degraded land must also be included in the spatial planning process, and its use should be prioritized over forested areas in the issuance of oil palm location permits (*Izin Lokasi*). In addition, financial incentives in the form of subsidies for use of degraded areas. This initiative will need to be linked to classical REDD payments or reclassifications under the spatial plan to ensure the original forest concession is not converted in the future by other activities.

Using degraded land is a relatively low cost opportunity to reduce emissions, with societal costs<sup>7</sup> of less than USD 10 per abated tCO2e. The direct costs of cultivating oil palm on degraded land are roughly equal to cultivation on forested land. Forest concessions do offer a one-time revenue from the harvesting of the timber, which can cover the capital to establish the plantation. However, this is not the biggest driver for palm oil companies; in fact, many report that unless there is an associated timber company, they find it difficult to sell the timber or the community will claim it. They report that the biggest cost of degraded land is the indirect time and compensation needed to reach agreement with the larger number of settlers on these lands.

Emissions from decomposing peatland can be reduced through the implementation of a water management system and peat rehabilitation efforts, which can yield 7.1 MtCO2e in abatement. Water management limits the depth to which the peatlands are drained, from 100 cm to 70 cm for example. While best practices are still being researched, dam and canal systems can better manage water tables in palm plantations. These need to be based on an assessment of the entire hydrological conditions around a peat dome; as peat domes are integrated systems,

<sup>7</sup> Societal cost doesn't include transaction costs (e.g., compensation payments for land use rights of communities), which could be significant, especially as a large number of smallholder communities would be involved

improving water management in one area, the deep center for example, will not be productive if drainage continues in another, the shallow periphery for example.<sup>8</sup> Such measures are relatively low cost at less than USD 1 per abated tCO2e. In addition, good water management can help reduce the risks of flooding in the wet season and drought in the dry season and therefore result in higher crop yields.

**Yield improvements can act both as an abatement measure (3.3 MtCO2e) as well as a tool to increase the sector's economic contribution.** In terms of abatement, yield improvements would allow the use of a smaller plantation area to achieve the same CPO production target, and thus could potentially reduce the area under cultivation, assuming good planning. If East Kalimantan reaches a similar yield level to Indonesia's national average, it could reach a production of 3.8 million tons of CPO<sup>9</sup> with 100,000 fewer hectares of plantations than at current yield levels. Yield improvements in isolation are unlikely to cause a decrease in plantation expansions; in fact, they could encourage expansion as palm oil becomes even more profitable. Therefore, yield improvements must be done in conjunction with strict planning on the use of lands for palm oil, targets set on production and not planted lands, and classical REDD payments to protect forests that would have otherwise been needed for palm oil expansion.

Avoiding emissions from deforestation and forest degradation through a concession buyout scheme could provide 3.2 MtCO2e of abatement annually. The idea behind concession buyouts is that local communities and concession holders would be paid for not starting or continuing economic activities that result in deforestation or forest degradation. While REDD+ payments could be part of the above initiatives, concession buyout payments would focus only on buying out a palm oil concession when there are no other options to relocate the palm oil plantation, Concession buyouts can be extremely expensive if concession holders and local communities insist on being compensated for the full opportunity cost of the lost palm oil plantation. Such an approach would cost approximately USD 16,000 to 21,000 per ha or USD 19 to 28 per avoided tCO2e depending of oil palm yields and avoided emissions. It should therefore only be applied in areas where few alternative opportunities for economic development exist, or to prevent the conversion of areas with high carbon and conservation value, such as primary forests and peatland or areas of cultural heritage for the province's indigenous peoples.

Costs for reducing carbon emissions within the palm oil sector are, with the exception of a plantation concession buyout, relatively cheap if calculated on a per ton of abated CO2e basis. However, given the sheer seize of the overall abatement captured, total costs reach considerable levels of up to USD 200 million per year (EXHIBIT 17).

#### **Pilot Projects**

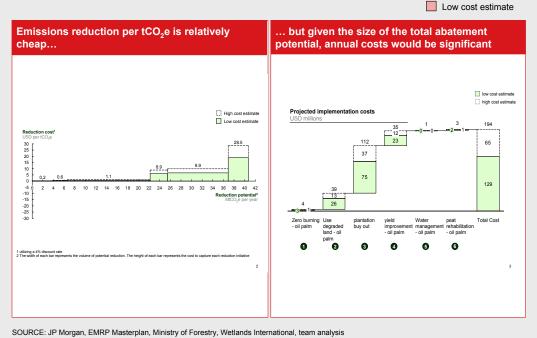

**Pilot projects will help to identify and overcome existing challenges and showcase the potent combination of emission reduction and economic growth.** Pilot projects should be developed to achieve quick and significant emission reduction as well as further economic development. Pilot projects need to be selected with local stakeholders and be based on several criteria, including the potential abatement as well as the level of support of stakeholders with land tenure and land-use rights. We have identified preliminary pilots by using the first criteria of abatement potential. Three recommended pilot project are as follows: work with the 10 largest holders of oil palm location permits (izin lokasi) in the province to relocate onto degraded land; implement a zero burning policy in areas historically prone to fire; and improve water management standards on peatland with the five largest active oil palm concession holders.

<sup>8</sup> Peat domes are in the center of a coherent hydrological system and are normally areas with the highest peat thickness, which control the water flow within the peatland

<sup>9</sup> East Kalimantan's business-as-usual production level at current yield rates is 3.8 million tons of CPO with 1.25 million ha under production

## Significant financial resources are required to reduce emissions from the palm oil sector

## The proposed pilot projects could yield as much as 375 MtCO2e of avoided emissions

**by 2030.** The increased use of degraded land could alone result in an avoided deforestation of 250,000 ha. The immediate emission reduction resulting from zero burning and water management will be relatively small with annual avoided emissions of 14 MtCO2e and 2 MtCO2e respectively however, the accumulated avoided emissions will become significant at 280 MtCO2e and 40 MtCO2e respectively by 2030. A moratorium on new licenses on forested areas and peatland is a proposed national policy<sup>10</sup> and could accelerate the above pilots.

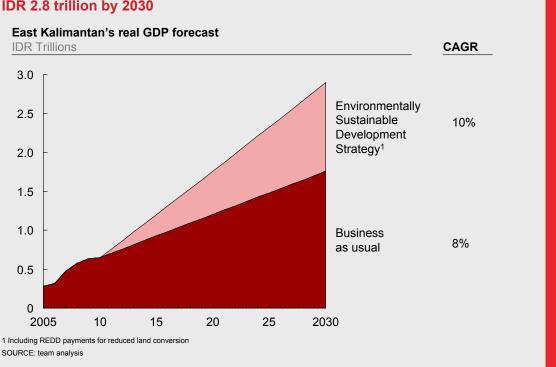

#### **GDP** Potential

The GDP contribution from palm oil is growing from the expansion of concessions, yet there is potential to increase growth above business-as-usual from raising productivity and capturing more downstream activities. The expansion of oil palm plantations will result in a tripling of current GDP contribution under a business-as-usual scenario. Improving yields and developing downstream manufacturing could provide an IDR 1.1 trillion of GDP in 2030, equal to 60 percent of the business-as-usual forecast for palm oil GDP (EXHIBIT 18).

**Current palm oil yields can be improved by 9 percent.** Average CPO yields in East Kalimantan's plantations are 3.1 tons per ha at present, which is below Indonesia's average of 3.5 tons of CPO per ha.<sup>11</sup> Lower yield rates are partly a result of lower natural soil fertility than other in provinces, e.g. the volcanic soils in Sumatra, but also a result of better inputs, such as fertilizers, and practices in those plantations. There are substantial productivity differences within East Kalimantan whose independent smallholders have much lower yields regardless of

<sup>10</sup> On May 28, 2010, a REDD+ partnership between Indonesia and Norway was announced, in which Norway pledged USD 1 billion towards REDD+ readiness programs and as a contribution in return for verified emissions reductions. At the same time, Indonesia committed to a two-year suspension of new concessions on forested land and peatland

<sup>11</sup> BPS - Indonesian palm oil statistics 2009

Including financial transfers for REDD, GDP from palm oil could increase to IDR 2.8 trillion by 2030

location. Raising yields in East Kalimantan up to Indonesia's average would result in 9 percent higher production from a given hectare of oil palm plantation, which would represent a significant additional contribution to GDP. Yield improvements might also be seen as a way to decrease the demand for converting land into oil palm plantations, which could result in lower emissions from the conversion process. However, yield improvements will not result in additional employment, as the number of employees needed within the labor-intensive palm oil sector is more directly related to area planted than output.

Box 1 discusses a 10-step approach to palm oil productivity improvements in Harapan Sawit Lestari Estate in West Kalimantan.

### Several opportunities exist for investing in the downstream manufacturing of CPOderived products, which range from food oils and biofuels to oleochemicals.<sup>12</sup> Our

conversations with potential investors have largely ruled out downstream manufacturing in food oils as companies prefer to process these near their consumer markets. We have focused on increasing the production of oleochemicals but, according to investors, a number of regulatory and fiscal obstacles discourage new investments in this area. Whereas Malaysia uses differing export duties to promote refined palm oil products over crude palm oil, Indonesia does not. In addition, good transportation is important for downstream processing. The lack of seaports with refined palm oil handling capacities and sufficient roads to enable fast transportation to centrally located refineries, also act as a disincentive to downstream manufacturing (EXHIBIT 19). We have identified improved infrastructure as a requirement to attract further investments in downstream refining.

Biofuels might be a sizeable opportunity as demand is rising fast, especially in Europe. The European Union has recently released new criteria that oil palm plantations have to meet if they

<sup>12</sup> Oleochemicals are used in soap products such as detergent, toothpaste, shampoo, and face soap

## Box 1

## Palm oil Productivity Improvements in Harapan Sawit Lestari Estate in West Kalimantan

Palm oil yields in Kalimantan lag behind their potential considering that the region's soil, climate conditions, and available planting materials. The Best Practice Management project implemented in Harapan Sawit Estate illustrates that impressive yield improvements in oil palm can be achieved by a targeted 10-step approach:

- · Complete crop recovery by strict control of harvesting activities to eliminate crop loss in the field
- Harvest intervals controlled at seven-day intervals
- Proper access for harvesting (infield paths, foot bridges, road access)
- Continuous maintenance of correct canopy conditions by removing fronds at harvest and implementing two rounds of pruning per year
- Ground cover management to provide adequate soil cover but provide harvesters and other field workers with unimpeded access
- Adequate in-field drainage and outlets
- Recapitalization of soil phosphorus with one-time application of 1 t per hectare of reactive tock phosphate
- Timely application of standard fertilizer programs
- Application of empty fruit bunch mulch (40 t per hectare)
- Relentless drive by management to maximize yield by eliminating field constraints

Following the approach, fresh fruit bunch yields in trial blocks increased rapidly after implementation of best practice guidelines by 4 t per hectare due to complete crop recovery. Additional FFB increases of 2 t per hectare can be explained by better agronomic management and reached 35 t per hectare in 2007.

(Fairhurst, McLaughlin (2009) Sustainable Oil Palm Development on Degraded Land in Kalimantan)

## **Box 2** Roundtable of Sustainable Palm Oil (RSPO)

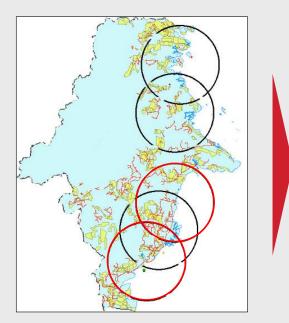

Palm oil yields in Kalimantan The Roundtable of Sustainable Palm Oil consists of oil palm growers, downstream manufacturers but also financing institutions and non-governmental organizations. In 2007, the RSPO has, after a long period of consultations, published more than hundred principles and criteria which ensure sustainable production of oil palm. While the majority of large Indonesian oil palm growers and palm oil producers are members of RSPO only a couple of companies, e.g. WILMAR and Cargill, have received formal RSPO cerification for selected plantations.

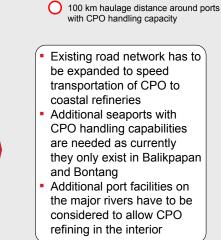

have the intention to export CPO or biofuels to Europe. Those criteria are in line with our current thinking related to a better utilization of our degraded land. The consequent implementation of those criteria could therefore open markets and provide a competitive advantage compared with other Indonesian provinces.

It is important that we implement safeguards to ensure that greater downstream processing does not lead to increased demand for palm oil that leads to increased deforestation for new concessions. This can be avoided partly by timing the development of downstream facilities only

after the identified abatement measures and policies are implemented. Locating any processing unit near palm oil concessions on degraded lands will also help as transportation costs will favor the closest concessions as sources. Finally, requiring the downstream processing facilities to use only certified sustainable palm oil (RSPO) can mitigate these risks (Box 2).

## East Kalimantan needs to improve its infrastructure to attract downstream investment

SOURCE: ICF, team analysis

#### **Required Policies and Institutions**

**Implementing these initiatives to reduce emissions and improve the growth of palm oil will require substantial changes from business-as-usual practices.** Four institutional and policy reforms will be critical for capturing the abatement potential from the palm oil sector (EXHIBIT 20).

#### Holistic and integrated spatial planning is needed to optimize land use for palm oil.

The existing spatial planning approach of East Kalimantan does not take into account climate change or ecological criteria. For example, forested areas are allocated to non-forestry use (*Areal Penggunaan Lain, APL*), while large areas of degraded land within the forest estate (*kawasan hutan*) are officially designated (and therefore managed) as permanent forest areas. Going forward, a broader spatial planning approach is required that incorporates environmental, economic, and social factors. The main goal for the new spatial planning approach should be to identify degraded areas (including the size of the area, soil type and suitability for different land uses, land ownership, and current land use) outside and inside the forest estate. This will enable the prioritized use of degraded land for economic development. The permanent forest estate should comprise actual remaining forests. Spatial planning consequently has to happen in much closer cooperation between the local planning agency (Bappeda), the Indonesian Ministry of Forestry, and local communities. The inclusion of local communities in the overall spatial and economic planning process has to follow a set of standards known as free, prior, and informed consent (FPIC). This approach has been developed to respect the rights of indigenous communities and can help reduce or prevent social conflicts related to land use in an area.

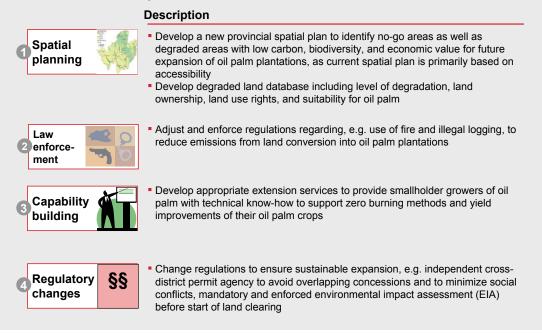

#### Exhibit 19

Law enforcement is required to ensure policies and changes are fully implemented. At

present, at least 60 oil palm concessions in the province are operating without the full set of legal permits required to do so (Box 3). It is essential for the future development of the palm oil sector that existing regulations regarding permits, the use of fire for land clearing, and illegal land clearing are enforced. Without enforcement, the lowest cost and quickest option to establish a palm oil concession would be to pay a bribe to plant on forest lands. We are committed to the national anti-corruption policies and thus enforcement must have strict and visible consequences. Our efforts will also help to gain the trust of international consumers and promote the image and integrity of oil-palm-derived products produced in Indonesia.

#### Exhibit 20

## Addressing critical enablers is required for successful emission reduction in the oil palm sector

**Capability-building is needed** to support the necessary behavioral change required. Emission reductions need to go hand in hand with productivity improvements so individual stakeholders gain benefits from their efforts to reduce emissions. We recognize East Kalimantan needs to provide smallholder farmers with training and technical support, as well as give them access to input components required for growing oil palms, such as cheap fertilizers and premium seedlings that will result in improved yields, lower production costs, and higher incomes.

**Regulatory changes are also required to support change in the palm oil sector.** At present, granted concessions exceed the total land area of the province excluding protected forests. This is a result of different agencies and levels of government being involved in the concession licensing process without common datasets or sufficient coordination. Providing an additional mandate and authority to the provincial planning agency *Bappeda* to track and give final approval for new concessions could help reduce duplication of concession licenses in the province and thus help reduce land-use conflicts. In general, such decision-making is pushed down to the lowest level of government as local governments have more on-the-ground knowledge and greater responsiveness to local stakeholders. However, in this case, the need to coordinate among different agencies issuing permits as well as to optimize land across all of East Kalimantan requires a central coordination effort. While there is the potential of a slightly longer bureaucratic process;

Box 3

## The Case of Oil Palm Permits and Related Area Consumption

Permits for oil palm concessions are generally issued by the head of the district government, and operators require three significant steps to legally operate a concession. At present, the official target formalized in the long-term strategic plan is to have an additional 1 million ha of oil palm plantations planted by 2025.

- **Location Permit** (*Izin Lokasi, IL*) is a preliminary boundary setting of a plantation, which is issued by the district leader (Bupati or Walikota) based on a recommendation by the provincial governor. At present, location permits for oil palm plantations in East Kalimantan cover an area of 3.2 million ha, of which more than 400,000 ha are located on peatland. In the last six months, the area for location permits increased by more than 350,000 ha.
- **Plantation Business Permit** (*Izin Usaha Perkebunan, IUP*) is issued by the Governor in case of cross-district plantations or by Bupati or Walikota if not and requires an Environmental Impact Assessment (AMDAL). Although location permits and plantation permits are formally linked together and both are required, many companies operate with only one of the permits.
- **Plantation Operating Permit** (*Hak Guna Usaha, HGU*) is issued by the national land agency (BPN) and is the final step for legally operating an oil palm concession. Approved and active plantations with HGU cover approximately 465,000 ha at present, while HGUs have been issued but not activated for another 300,000 ha.

however, this does not need to be the case. The new process could actually translate into a clear competitive advantage for East Kalimantan in its efforts to attract new investments by reducing the legal complexity and time consuming delays facing oil palm investors.

## **FORESTRY SECTOR**

Forests have always been an important resource for East Kalimantan: valuable timber is collected from legal logging, industrial plantations provide Acacia, Eucalyptus, Teak, and other tree species, communities harvest non-timber forest products, and forests provide vital ecological and environmental services such as watershed protection, biodiversity, habitat for countless species. Yet, since the 1960s East Kalimantan's production forests have experienced unsustainable rates of logging, which have resulted in the degradation of the forests. Those high logging rates could not be sustained as reserves of valuable timber were depleted and tree growth was insufficient to replace stocks. Thus, the forestry sector has declined since the mid 1990s in both relative and absolute terms in East Kalimantan's economy.

With the exception of two FSC-certified concessions, East Kalimantan's logging concessions do not meet international best practices for reduced impact logging (RIL). Unsustainable logging practices together with the conversion of natural forest into timber plantations and the decomposition of degraded peatland within the forestry estate (*Kawasan Hutan*) result in estimated annual net emissions of 45 MtCO2e, which makes the forestry sector the third largest emitter in the province.

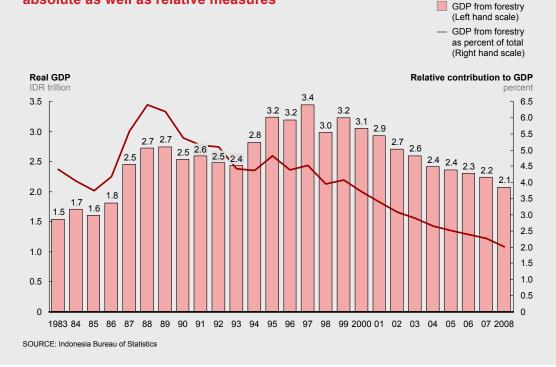

Significant reductions in forestry emissions are possible through the implementation of RIL practices, more efficient use of areas already designated as timber plantations, better water management in existing forestry concessions in peat areas, and a moratorium on granting new concessions on peatland. Increasing productivity in existing timber plantations and RIL within the logging concessions would enable a sustainable supply of wood to support an expanded downstream industry, which in turn would increase local employment by an estimated 40,000 to 60,000 new jobs and contribute up to IDR 20 trillion to provincial GDP.

### **Current Context**

**The forestry industry has been in a slow decline for over a decade.** Still, forestry is East Kalimantan's largest sector in terms of land use, occupying an area of more than 7.5 million ha. In contrast to the large area deployed, the economic contribution of the forestry sector<sup>13</sup> is relatively small at approximately IDR 2.1 trillion GDP at present. This contribution to GDP has been steadily declining since the late 1990s when it peaked at IDR 3.4 trillion (EXHIBIT 21).

#### Exhibit 21

GDP contribution of the forestry sector is declining since the 1990s both in absolute as well as relative measures

#### The decline in forestry is due to historical overlogging as well as low productivity in

**plantations.** Many of the production forests (*Hak Pengusahaan Hutan, HPH*) have been over logged and illegally logged in the past and can today supply only a small number of high-value logs. Furthermore, East Kalimantan's timber plantations (*Hutan Tanaman Industri, HTI*) have had extremely low productivity levels, as a result of poor management practices, e.g., the inefficient use of silviculture. HTI productivity and utilization has also been slowed by lower than expected demand for timber (especially pulpwood) within East Kalimantan, as planned expansions and further investments in downstream processing capacities have not been realized.

**Net emissions from forestry are significant at approximately 45 MtCO2e.** Four major landuse related factors are driving emissions from the forestry sector: forest degradation from legal logging, deforestation from conversion to timber plantations, peat decomposition from logging and conversion on peatlands, and fires used for clearing land and debris (EXHIBIT 22). The forestry sector is also the largest absorber of CO2e in East Kalimantan, absorbing 34 MtCO2e in 2010.

The degradation of East Kalimantan's production forests (HPHs) is the largest single source of emissions within the forestry sector at 34 MtCO2e annually. Current logging techniques cause massive collateral damage and result in the subsequent death of many of the

<sup>13</sup> Excluding wood products and pulp and paper manufacturing

-: Lit 00

	Emissions Mt CO <sub>2</sub> e	Description	
Forest degradation	34	<ul> <li>Current planned logging activities are leading to a permanent loss of carbon in East Kalimantan's production forest</li> <li>Illegal logging is contributing significantly to forest degradation, however there are many uncertainties about size of impact</li> </ul>	
Deforestation	24	<ul> <li>Planned and unplanned conversion of natural forests result in significant net emissions even taking sequestration of plantations into account</li> </ul>	
Peat decomposition	17	<ul> <li>Drainage channels used for dewatering of peat transportation of timber and logging equipment lead to the decomposition of the peat organic matter</li> </ul>	
Fire	13	<ul> <li>Fire is used for land conversion but also land clearing from wood residues at the end of the rotation cycle</li> </ul>	

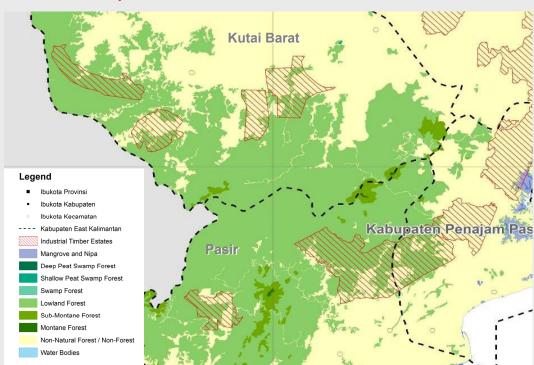

SOURCE: Ministry of Forestry Indonesia; Dinas Kehutanan; Wetlands International; Van der Werf et al 2008 Team analysis

trees left behind when saleable timber is extracted. Emissions from this collateral damage to the forest is several times the emissions from the actual harvested trees for sale. Such damage to surrounding forest is not inevitable, but can be explained by unsustainable logging practices, minimal harvest planning, a lack of training for forest workers, a lack of management capabilities, and use of inappropriate skidding technology. All of the above result in low growth of the remaining trees. Poor logging techniques can cause the net loss of 30 percent of the initial carbon stock of a forest over a logging cycle.

The expansion of timber plantation area in recent years has resulted in large areas of natural forest being converted, causing emissions of 24 MtCO2e in 2010. Conversion of natural primary and secondary forests into timber plantations results in a net carbon loss of up to 70 percent of the initial carbon stock of the forest, making conversion the second largest emission source of the forestry sector.

Emissions from peat decomposition are smaller than in neighboring provinces, such as Central Kalimantan, yet still result in 13 MtCO2e emissions in 2010. East Kalimantan's peatlands are partly covered with timber plantations and logging concessions. Peat soils in these areas are degraded through drainage to allow for logging and harvesting activities. As the area of degraded peatland increases with new concessions, emissions are expected to reach 17 MtCO2e in 2030.

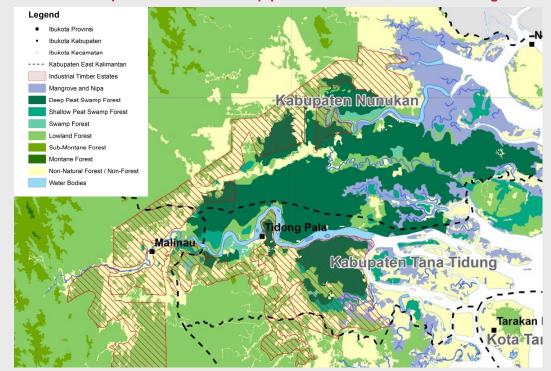

**Fires within the borders of production forests, especially on peat soils, are another significant source of emissions, approximately 11 MtCO2e in recent years.** The number of hot spots varies from year to year as fire is heavily influenced by rainfall and other weather factors. However, fires spread through degraded areas, thus these emissions are expected to increase to 13 MtCO2e in 2030 under a business-as-usual scenario with increased forest degradation. Besides emissions, fires cause massive economic losses, not least by destroying merchantable timber. The World Resource Institute estimated the financial losses caused by the ravaging fires

Planned timber plantations on natural forest in Kutai Barat and Pasir

## Exhibit 24

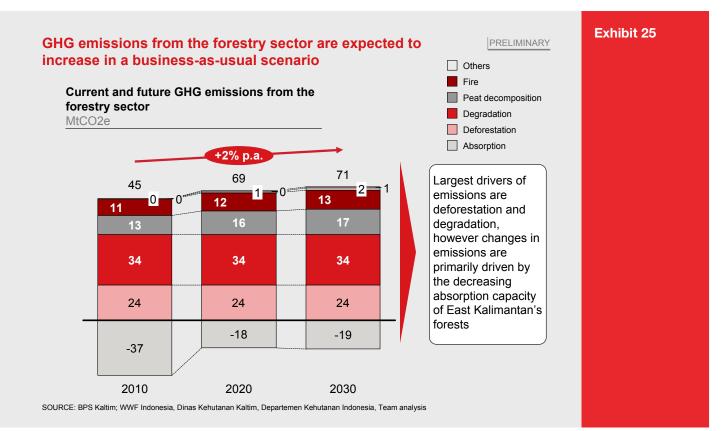

## Some timber plantations cover deep peat in Nunukan and Tana Tidung

across Kalimantan in 1997 and 1998 to be in the range of USD 3 to 5 billion.<sup>14</sup> In addition, fires damage the environment as well as the health of our people, leading to high levels of respiratory problems and indirect costs.

**Counteracting these emissions, East Kalimantan's forests are a major source of carbon sequestration (or carbon sink).** Based on different scientific publications and growth rate assumptions published by the Ministry of Forestry, it is estimated that East Kalimantan's secondary forests and timber plantations are sequestering 37 MtCO2e annually at present, of which approximately 24 MtCO2e is sequestered in natural secondary forests.

In a business-as-usual scenario (EXHIBIT 25) net emissions from forestry will grow from 45 to 71 MtCO2e by 2030. Emissions from forest degradation within logging concessions will continue at roughly the same pace as will emissions from the continued conversion of forests to timber plantations. Once drained, peatlands continue to degrade over many years, and so it is expected that emissions from peat decomposition as a result of drainage will rise and the damage from fires will also increase in newly opened up peatland. In addition, absorption from East Kalimantan's secondary forests and timber plantations will be reduced to only 19 MtCO2e by 2030 as the overall size of the forest area decreases and timber plantations reach the end of their rotation cycle.

#### **Abatement Potential**

**The forestry sector has the potential to become a net carbon sink over time.** The forestry sector is unique; its abatement potential is larger than its estimated future gross emission levels. This abatement potential consists of the implementation of reduced impact logging in the production forest (HPHs), better water management and rehabilitation of peatland, and reforestation (EXHIBIT 26).

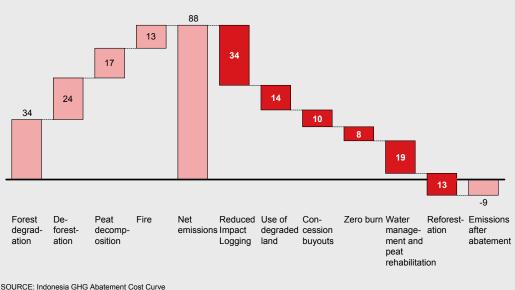

<sup>14</sup> World Resource Institute (2001) - State of Forests: Indonesia

## Technically East Kalimantan's forestry sector could become carbon neutral in 2030

EmissionsAbatement

Forestry sector 2030 BAU gross emissions, net emissions after abatement, and abatement levers  $\ensuremath{\text{MtCO}_{2}e}$ 

#### Reduced impact logging (RIL) is the largest abatement opportunity and could yield 34

**MtCO2e by 2030.** Reduced impact logging could be attractive to private companies as it allows the same amount of commercial timber to be extracted. Yet, the introduction of new harvesting techniques will require investment – training, initial capital, and monitoring. Currently, production forests, or HPHs, are largely ungoverned as they fall under the control of the national Ministry of Forestry, which lacks sufficient provincial-based staff to monitor concessions. Creating forestry management units *(Kesatuan Pengelolaan Hutan – KPH)* across the provinces to increase monitoring could be a powerful tool to strengthen monitoring and control and improve harvesting planning and practices, especially concerning the skidding<sup>15</sup> of timber. Investments in roads and skidding infrastructure are required to reduce the skidding distances and thus reduce damage caused during logging of the remaining forests. Additional investments in skidding technology and the training of forest workers are also required. The cost for implementation is relatively low compared to the abatement potential, approximately USD 0.5 to 2.5 per ton of abated CO2e. Still, for the timber companies, this translates into required investment estimated at approximately USD 50 to 250 per ha.

### Utilizing degraded land for expansion of timber plantations would yield 13.9 MtCO2e

of abatement. Using degraded land within and outside the forest estate for expansion should be prioritized for future timber plantations wherever possible. If not suitable for rehabilitation, degraded areas within the forest estate should definitely be used for future expansion of timber plantations. However, for other degraded lands, a new planning exercise will be needed to select the type of land use that holds the highest economic value for East Kalimantan.

<sup>15</sup> Skidding is describing the process of hauling one or several felled logs with e.g. a bulldozer to an area accessible for other means of transportation e.g. rivers and major roads.

**Utilizing concession buyout schemes could provide 9.8 MtCO2e in abatement.** The use of standalone concession buyout schemes is the last option due to its high costs. This approach targets land owners or concessionaires and pays them for not starting economic activities, such as converting forests into pulpwood plantations. Without providing a substitute, such as degraded land or improved productivity, concessions holders may need to be compensated for the opportunity cost of the lost plantation (assuming all proper permits were received). This approach comes at relatively high cost, approximately USD 9 to 14 per avoided tCO2e in the case of *Acacia* and even more for more valuable woods like Teak or Meranti. A compensation scheme that only covered historical costs and expenses would result in much lower cost per ton of abated carbon,

**Improving yields in timber plantations could result in less expansion into forest, but only if coupled with other safeguard measures.** Growth rates within East Kalimantan's HTIs are below best practice yields achieved in other parts of Indonesia. In 2008, harvesting targets for pulpwood plantations according to the Provincial Forest Ministry (*Dinas Kehutanan*) indicate an annual growth rate of approximately 20 cubic meters per ha. Best practice examples in Sumatra achieve annual growth rates for *Acacia mangium* of 40 cubic meters per ha. Given differences in soil quality, however, a more conservative target growth rate of 25 to 30 cubic meters per ha seems more feasible. Increasing productivity would allow for increased production with less forest conversion: approximately 150,000 ha less than in the business-as-usual scenario and result in avoided emissions of 120 MtCO2e over a period of 20 years.

Increasing growth rates can also be accomplished by using intensive silvicultural methods like thinning, better planting techniques, a better selection of seeds, and improved nursery techniques for seedlings. However, productivity improvements alone would not necessarily lead to less HTI expansion; in fact, it could make the sector more attractive and increase investment and expansion. Increased productivity would need to be coupled with additional measures to protect the available forest, for example REDD+ payments if reduced deforestation could be proven.

#### 12.5 MtCO2e of abatement is possible from reforestation and forest rehabilitation.

Degraded forests can be reforested and rehabilitated with new plantings and result in increased carbon sequestration. There is approximately 1.5 million ha of slightly critical land *(agak kritis)* located within the forest estate; these areas have forest cover of 50 to 60 percent, and thus should not be used for land swaps for timber concessions but instead fully reforested. We have already launched a One Man Five Tree replanting program to engage the whole province in reforestation as well as raise awareness. To achieve the 12.5 MtCO2e abatement potential, approximately 35 to 40 million trees need to be planted each year to restore the degradation caused by non-sustainable logging practices.

#### Reforestation and forest rehabilitation only results in carbon sequestration if the

**replanted lands are set aside for conservation.** Timber plantations are considered carbon neutral as nearly all carbon sequestered as trees grow is lost once they are harvested; thus replanting for timber plantations yields no permanent abatement of emissions. Reforestation and forest rehabilitation comes at a relatively high cost of approximately USD 2 to 5 per tCO2e. However, fostering natural regeneration (if the remaining trees provide enough potential) by weeding and other techniques to increase the viability of tree seedlings could reduce the costs substantially and should be the preferred option for rehabilitation wherever possible.

Water management and peatland rehabilitation initiatives can produce 17 MtCO2e of abatement. The goal is to minimize drainage in logging and timber concessions on peatland to 50 to 70 cm below the peat surface. High growth rates of Acacia are possible at this level; any further drainage would result in higher emissions from peat decomposition, while lower drainage would result in decreasing yields. Drainage to 50 to 70 cm below the surface also allows for the transportation of pulpwood in the drainage channels. Proper water management requires an assessment of the hydrological conditions around the peat domes and the construction of dams and sluice gates to regulate the water level to allow transportation of felled timber. In addition,

water management can help to reduce the risk of flooding in the wet season and prevent the risk of drought in the dry season, events that often reduce yield and therefore result in financial losses.

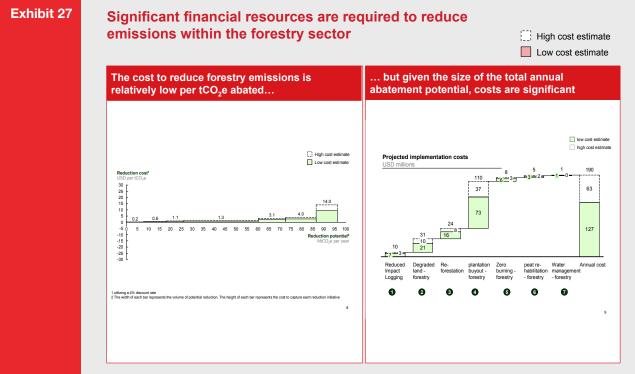

Water management is relatively low cost, with an associated cost below USD 1 per

**abated tCO2e.** While the restoration of peatlands via water management is low cost, replanting degraded peatlands is relatively expensive with costs of USD 500 to 1,100 per ha, or USD 2 to 5 per ton of sequestered CO2e. Fostering natural regeneration of existing tree cover could reduce the replanting costs significantly and should be applied wherever possible.

Fire prevention and management could yield 8 MtCO2e in abatement annually by 2030.

The prevention of peat fires has a significant emissions abatement potential at a relatively low cost of less than USD 1 per avoided tCO2e. Major emission reductions could be achieved by implementing a zero burning policy to prevent encroachment of fires into plantations and logging concessions, providing appropriate and practical equipment (and, if appropriate, financial incentives) for fire fighting, developing appropriate early-warning systems based on fire risk status and field-based fire detection, strengthening fire brigades, ensuring strong enforcement and large penalties for rule violations, and building public awareness of the economic and social costs of forest fires in the province.

Costs for reducing carbon emissions within the forestry sector are, with the exception of a plantation concession buyout, relatively cheap if calculated per ton of abated CO2e basis, averaging to USD 1 to 2. However, given the sheer size of the overall abatement captured, total costs reach considerable levels of up to USD 190 million per year (EXHIBIT 27).<sup>16</sup>

<sup>16</sup> The two already FSC certified concessions of PT Sumalindo and PT Intracawood have not been considered as pilots, however those concessions could be models for future sustainable logging activities

A h a t a ma a m t 1

## **Pilot Projects**

## **Pilot projects have been identified for five abatement initiatives across the province, which could result in annual emission reductions of 34 MtCO2e.** Pilot projects for implementation will need further screening to take into account important criteria such as support from companies and the communities involved and potential biodiversity benefits. A first list of

potential pilot projects has been identified to target opportunities providing the largest abatement with quick, significant emission reductions and further economic development by (EXHIBIT 28).

## Identified potential pilot projects could reduce annual emissions by 34.4 Mt CO<sub>2</sub>e

<ul> <li>Pilot RIL based on new harvest planning system, skidding track layout, and harvesting technology in the 3 largest concessions in each district</li> <li>Implement empowered forest management unit across the province overseeing 10,000 ha of forest per employee</li> <li>Develop pilot projects to establish timber plantations on degraded land in Berau, Kutai Barat, Kutai Kertanegara, and Kutai Timur with</li> </ul>	12.0
land in Parau, Kutai Parat, Kutai Kartapagara, and Kutai Timur with	74
Degraded land support of TNC, WWF, and GTZ to capture potential of approx. 50% of total degraded land area	7.4
Concession buyouts • Develop pilot projects in Berau and Kutai Barat to avoid ongoing emissions from forest degradation and inactive concessions	3.0 <sup>1</sup>
<ul> <li>Peatland in Nunukan</li> <li>Rehabilitate drained and degraded peatland within concessions</li> <li>Implement water management in active concessions</li> </ul>	4.0
<ul> <li>Rehabilitate slightly critical land in Kutai Kertanegara, Kutai Timur, and Kutai Barat to restore ecosystem services and carbon sequestration</li> </ul>	8.0

2 with sufficient international and domestic funding for REDD

SOURCE: team analysis

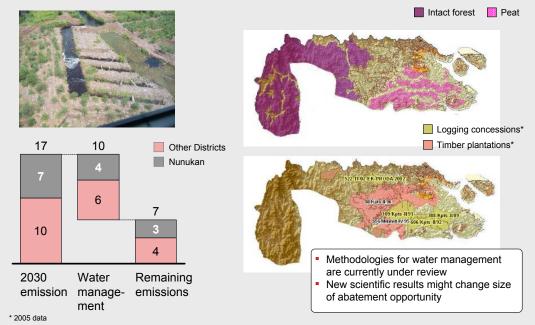

The potentially largest pilot group would be to implement RIL within the 10 largest logging concessions. Those concessions cover an area of more than 1.7 million ha, and focusing on cooperating with those companies to implement RIL within those concessions could reduce emissions by approximately 12 MtCO2e p.a. while maintaining harvesting volumes at least at current levels. Seven concessions identified for the pilot are held by private companies, and three

concessions are held by the state owned enterprise PT Inhutani.

Water management in active plantations and logging concessions and peat rehabilitation in inactive ones could be piloted in Nunukan. Nunukan holds the largest areas of deep peatland within the province. Action to protect and minimize degradation of those deep peatlands is urgent, as nearly the total area is already covered (but not yet developed) with concessions (EXHIBIT 29). Effective action on peatland in Nunukan could result in a significant emission reduction for the forestry sector of up to 4 MtCO2e p.a.

Other pilot projects include using degraded land within the forest estate for timber plantations. Districts like Malinau or Berau, have large and undisturbed forest cover, but their forests are under severe threat. They could be prepared for a REDD payment scheme. The latter project could also be part of the nationwide pilot to be launched in 2011 in accordance with the Norway–Indonesia REDD+ partnership signed on May 28, 2010. None of the potential pilot projects described above should slow economic growth; concession holders will be allowed to proceed with their economic activities.

## **GDP** Potential

The economic decline of the forestry sector in East Kalimantan can be reversed through raising productivity and investing in downstream activities. These moves would increase the forestry sector's GDP by IDR 16 trillion by 2030 (EXHIBIT 31). The initiatives described earlier will reduce emissions from our current logging and harvesting activities, but such efforts should be complemented with efforts to extract more value from these activities. Currently, much of the felled timber from logging is left as waste in the forest: thiscould be further processed. After forests are converted to plantations, there are different opportunities to raise productivity within those concessions. And finally, much of East Kalimantan's timber is exported to Sumatra and Java where it is processed into higher value products such as pulp or furniture. East Kalimantan has the opportunity to capture a larger share of the downstream value-add going forward.

## Yield improvements in HTI, and increasing value added production could increase the GDP of the forestry sector to IDR 19.3 trillion by 2030

**IDR** Trillions CAGR 20 15 Environmentally Sustainable 5% Development 10 Strategy 5 **Business** -1% as usual 0 15 25 2030 10 20 2005 SOURCE: team analysis

**Improving timber utilization could yield IDR 0.7 trillion in additional GDP.** Currently, logging operations produce large volumes of waste. The logging companies currently sell to domestic plywood and veneer mills or other solid wood applications. These buyers are interested in only large diameter logs. Thus, large volumes of small-diameter wood (e.g., tree crowns) and wood residues are left behind in the forest after the trees are cut. A more efficient approach is to fully utilize the felled trees and thus gain higher revenues from a given land area. A common approach in Europe, North America, and Brazil is to use large-diameter wood for high-value applications (as is already done in East Kalimantan), but then to sell small-diameter wood and wood residue for lower-value applications like pulp and paper, board manufacturing, and the production of wood chips and wood pellets (EXHIBIT 32).

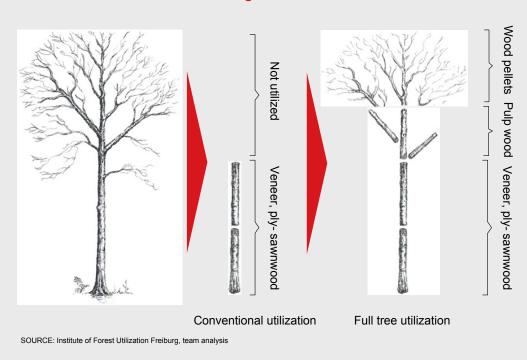

**Growth rates in East Kalimantan's timber plantations could be substantially improved and idle plantations brought back into production.** As noted earlier, growth rates in East Kalimantan's industrial pulpwood plantations are low compared with best practice benchmarks in other parts of Indonesia. The annual growth rate is around 20 cubic meters per ha, while up to 40

Utilizing trees fully can increase the value from logging activities and decrease harvesting waste

ILLUSTRATIVE

cubic meters per ha is achieved in other parts of Indonesia. Given differences in soil quality, a more conservative range of 25 to 30 cubic meters per ha is targeted.

Increased yields could also come from bringing idle plantations back into production. At present, East Kalimantan's pulpwood plantations cover an area of approximately 800,000 ha, the majority of which were established during the 1990s. In line with current environmental regulations, approximately 160,000 ha have to be set aside for nature conservation (e.g., watershed protection and wildlife corridors) while the remaining area could be used for economic purposes. In theory, these 640,000 ha could yield an annual volume of approximately 23 million cubic meters,<sup>17</sup> more than enough to supply a viable forest products industry. However, currently only 165,000 ha are actually planted, while the remaining area is degraded, and lies idle. Low productivity, and this low rate of planting mean East Kalimantan's annual harvest is only 0.7 million cubic meters. The continued conversion of natural forests into plantations is unnecessary for growth in the sector. Instead of expanding the overall plantation area, the focus should be on improving yields and ensuring that the area set aside for industrial timber plantations is fully utilized. Realizing this approach could increase annual sustainable wood production and the economic contribution from production forests by a factor of ten.

**Downstream manufacturing (IDR 8.5 trillion):** Several opportunities exist for the industry to move downstream into higher value-added production businesses. Based on future market developments, the largest opportunities are likely to be in pulp and paper and wood pellet production, which ideally would be located in close proximity of each other to lower costs of logistics, raw material, and energy. Additional opportunities for niche companies exist in production of high-value furniture (EXHIBIT 33).

<sup>17</sup> Assuming plantations planted with Acacia maginum and Eucalyptus species

Pulp and paper: In the pulp and paper sector, Indonesia has a proven track record of being world class in terms of production. The pulp mills in Sumatra are amongst the world's largest and lowest cost production sites.,They are extremely controversial from an environmental perspective as insufficient supply from plantations being heavily supplemented by timber cleared from natural forests. Sustainable pulp production in East Kalimantan would be competitive globally given its low costs and advantages of its location relative to the India and China markets for pulp.

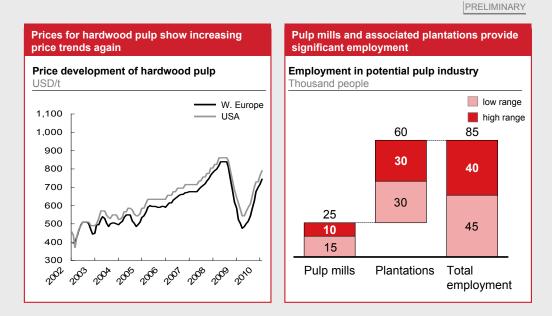

As described above, the area of East Kalimantan's industrial timber plantations is large enough to supply more than 20 million cubic meters of pulpwood if managed with best international practices. This volume would meet the full production requirements for the existing Kertas Nusantara pulp mill in Berau, approximately 6 million cubic meters per year, as well as provide another 2 million tons of market pulp.

The production of market pulp would result in a significant contribution to East Kalimantan's GDP and also provide significant working opportunities for our people (EXHIBIT 34). Prices for market pulp recovered quickly from the dip during the economic crisis in 2009 and have reached levels of nearly USD 800 per ton delivered to Europe or North America. At this price level, the production of 2 million tons of market pulp could result in revenues of USD 1.6 billion p.a. The number of employees required to run a pulp mill and the adjacent plantations is significant as well. Pulp mills in Sumatra employ between 30,000 and 50,000 people for the production of 1 million tons of pulp.

Significant safeguards would need to be put in place before the expansion of the pulp and paper production capacity. Increasing the demand for timber without first ensuring a sustainable supply will only lead to increased overlogging and deforestation. There are several options to ensure the pulp and paper mills use only timber from sustainable plantations. Investment loans for the mills could be routed through the IFC or other organization with established safeguard procedures. Timing the development of the pulp and paper mill to begin construction only after sustainable plantations have been planted is another measure. Even choosing an appropriate location will help; as transportation is a major cost driver for a pulp and paper mill, locating any expansion in an area of degraded lands will make nearby timber plantations the preferred source from a commercial perspective.

## Exhibit 34

## At current market prices, additional 2 million t of pulp will result in revenues of 1.5 billion USD annually and provide significant job opportunities

- Wood pellets: Wood pellets for bioenergy production is a rapidly growing market in Europe and other developed markets. Opportunities exist also in domestically, especially for Indonesia's increasing number of small-scale decentralized power plants. Given sustainable sources of wood supply (residue from logging operations and saw mills or dedicated biomass plantations) and a location close to a nearby pulp mill, which would enable synergies from wood logistics and excess steam and electricity, wood pellets are competitive even for export to Europe. A sizeable plant with a capacity of 200,000 tons could yield revenues of approximately USD 20 to 25 million at current market prices with a return on investment (ROI) between 16 and 22 percent.
- High-value furniture production: Moving downstream into high-value furniture production is an option for small to mid-scale plywood or veneer producers as it does not require the massive investments of the pulp and paper industry, which is based on large production volumes. Both international and domestic market opportunities exist, but complex logistics make local markets more attractive from a profit basis.

Overall, East Kalimantan is well positioned to develop its forestry industry with several downstream opportunities. Achieving high yields and utilizing wood resources better would enable East Kalimantan to provide the basis required to attract investments into the forestry industry. However, we will work to ensure that any changes to the forestry sector are based on sustainability. If a sufficient supply from sustainable sources cannot be achieved, we will not pursue expansion of

downstream manufacturing as it would result in further deforestation and forest degradation, as has happened in other provinces.

## **Required Policies and Institutions**

Several critical enablers are needed to implement the identified initiatives for reducing emissions and increasing GDP in the forestry sector. Four critical enablers have been identified. These include a new spatial planning approach, regulatory changes and enforcement, capacity-building to successfully implement sustainable forestry practices, and implementation of a reliable and up-to-date monitoring, reporting and verification system, which would be supported by the new forest management units.

**Spatial planning:** The existing spatial planning approach of East Kalimantan does not take into account climate change or ecological criteria. For example, forested areas are allocated to non-forestry use (*Areal Penggunaan Lain, APL*), while large areas of degraded land within the forest estate (*kawasan hutan*) are officially designated (and therefore managed) as permanent forest areas. Going forward, a broader spatial planning approach is required that incorporates environmental, economic, and social factors. The main goal for the new spatial planning approach should be to identify degraded areas (including the size of the area, soil type, suitability for different land uses, land ownership, and current land use) outside and inside the forest estate. This will enable the prioritized use of degraded land for economic development. The permanent forest estate should comprise actual remaining forests. Spatial planning consequently has to happen in much closer cooperation between the local planning agency (Bappeda), the Indonesian Ministry of Forestry, and local communities.

**Regulatory changes:** Current legislation regulating harvesting practices in Indonesia does not support sustainable forest management as it only focuses on volumes of merchantable timber and doesn't address the overall felling and skidding process. To be able to enforce RIL those regulations have to be broadened to consider the complete harvesting process. A new regulation published in 2009 by the Ministry of Forestry is trying to address sustainability, however the regulation is vague and not strong enough to enforce RIL. In addition, current regulations prohibit the felling of smaller trees for commercial purposes, i.e., those below 50 cm diameter at breast height (dbh). Changing those regulations would allow thinning, which can help focus the forest's future growth on the most valuable trees by providing enough light and space to foster natural regeneration. If properly done, thinning and improved natural regeneration result in higher growth rates and therefore better carbon sequestration. However, thinning and other intensive silvicultural treatments result in a loss of biodiversity as they focus on a small number of high valuable tree species and not necessarily on biodiversity. In the long term we need to seriously consider a complete replacement of logging in natural forests by sustainable timber plantations.

**Law enforcement:** Illegal logging – in the form of large-scale forest conversions into plantations without legal permits, logging levels exceeding the target given by the Ministry of Forestry, and illegal smallholder activities – remains rampant in East Kalimantan and is leading to high levels of deforestation and forest degradation. In order to better enforce the law, we need to employ additional forest rangers for the newly established forest management units (KPH), and ensure strict and visible consequences for illegal action, e.g., high fines and long jail terms.

**Monitoring, reporting, and verification (MRV):** All of the above efforts should be supported by an MRV system to assess the emission reduction efforts and to measure, report, and verify the impact of those efforts to a nationwide MRV system. In order to reduce transaction costs and increase the likelihood of carbon reduction projects attracting international carbon market payments for verified emission reductions, it is critical that the provincial government incorporates methodologies that have already been independently verified, are in line with national government regulation, and allow the establishment of a province-wide approach that includes local communities. Local communities could play a key role in ground-truthing satellite images in the field, which would also create additional jobs and increase income in local communities.

## **AGRICULTURE SECTOR**

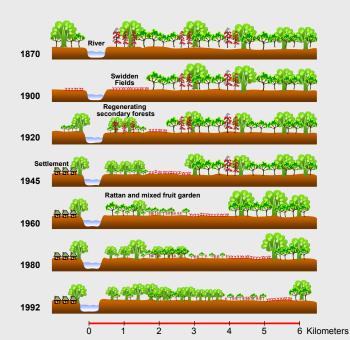

Agriculture remains an important part of East Kalimantan's development and is one of the most important opportunities to improve rural livelihoods. Although agriculture, excluding palm oil, represents only 4 percent of East Kalimantan's overall GDP, in some rural districts it accounts for 20 percent of GDP. Its impact on rural communities is even broader as it accounts for almost 20 percent of total employment. By bringing jobs and incomes to rural households, which are typically poorer than the average household in East Kalimantan, agriculture is one of the most effective anti-poverty economic development strategies; by some estimates, a 1 percent increase in agricultural GDP can translate into 6 percent more spending for rural households. Yet, current agricultural practices also led to significant emissions from land use, and there are substantial opportunities to reduce the sector's carbon footprint. In this section, the agricultural sector includes both production of food crops and estate crops but excludes palm oil, which is addressed in a separate section given its disproportionate size and growth.

#### **Current Context**

**East Kalimantan's agricultural sector is divided into food crops, dominated by rice production, and estate crops.** Over 178,000 ha of agricultural lands are planted with food crops, often for subsistence farming. Rice is by far the largest food crop, accounting for almost 90 percent of production by hectare. Estate crops, excluding palm oil, are roughly equal in area to food crops with 181,000 ha planted. Rubber, followed by cocoa and coconuts, are the largest crops accounting for 80 percent of planted areas. Compared to Java and Sumatra, agriculture is small in East Kalimantan, taking up just 2 percent of land and 4 percent of GDP, but is still important for rural communities.

Agricultural practices differ substantially by type of farming in East Kalimantan. There are four main types of farming in East Kalimantan, upland food crop production, lowland food crop production, perennial estate crop production, and swidden or shifting cultivation. These are not mutually exclusive as individual farmers engage in multiple types of farming. Lowland farming is dominated by irrigated paddy rice fields and common among Javanese migrants. Upland farming is conducted in rainfed, hilly areas; again rice is the most common crop, but its yield is almost half that of lowland rice. Perennial estate crop farming practices differ by the type of crop. For example, the pepper plantations common among Buginese migrants are typically developed for three to five years, after which the soil is depleted and must be restored or abandoned for new farmland. Rubber plantations, by contrast, take 10 to 15 years to reach peak productivity. Swidden or shifting cultivation involves the clearing of agricultural or forest land, typically by fire, cultivating the land for a short period until fertility or weeds decrease productivity, then shifting to a new area, eventually rotating back through fields as they have been restored. While conventional wisdom holds that shifting cultivation is a major force of deforestation and is inherently unsustainable, its impact depends on the length of the rotation. The swidden agricultural practices by Dayak tribes are considered more sustainable given their long rotation periods compared to swidden practices on lowland, smallholder estate crops, which have shorter periods.

Agriculture accounted for substantial emissions of 52 MtCO2e in 2005, primarily from its expansion into forests and peatlands. Agricultural processes, such as the fuel used to run farm equipment and transport crops, and methane release from flooded rice paddies, account for only 3.2 MtCO2e currently. The other 94 percent of emissions are due to the opening up of forest land for new agriculture (9.4 MtCO2e), use of fires to clear land and their spread and subsequent destruction of abandoned lands (31 MtCO2e), and peat decomposition from active and abandoned peatlands which have been opened and drained for agriculture (8 MtCO2e). These emissions are greatest in the districts of Nunukan, Kutai Kertanegara, and Kutai Barat, respectively.

Exhibit 36

## **Abatement Potential**

Agriculture can decrease its current CO2 footprint by 24 MtCO2 by 2030 through a policy of zero burning and the rehabilitation of peatlands. Smallholder fires represent a significant source of emissions. A zero burning policy could deliver 18.5 MtCO2 at a cost of USD 0.40 per ton (excluding implementation costs) through a program of alternative land clearing methods, rigorous fire prevention, and the use of local fire fighting brigades. Rehabilitating degraded peatlands that were opened for agriculture and then abandoned will provide 5.4 MtCO2 of abatement at a cost of USD 5.20 per ton.

A zero burning policy can reduce emissions from forest fires by prohibiting fire as a tool for land preparation, establishing fire brigades, and ensuring strong enforcement and large penalties for rule violations. On average, 250,000 hectares of land in East Kalimantan are burned each year. Pristine forest is virtually fire-proof, so the complementary strategy is to prevent land conversion of intact forests. Active agricultural lands are burned to prepare for planting, so fire prevention strategies would include investments in alternative tools for land clearing and training. These strategies should also aim to remove regulatory incentives that encourage fire clearing as a means to prove 'active cultivation' for the purpose of retaining concessions or proving ownership. Abandoned lands are quite vulnerable to fires that spread from active lands. Thus, an important element of fire fighting strategies is the expansion of community fire brigades which can quickly identity and deal with fire hot spots.

Rehabilitating peatlands can be done by adjusting and maintaining the water table at a more sustainable level and through reforestation and wetting of degraded peatland that has little food or feed production value. Smallholder agriculture requires draining peatlands by 50 cm on average, which results in exposed peat that reacts with oxygen and releases CO2e. For one ha of a smallholder plot, an average of 27 tCO2e is released annually assuming a drainage level of 50 cm. Building dam systems and applying best practices in water management can lead to a less destructive way of peatland utilization to a more sustainable level.

#### Pilots

Almost 80 percent of the abatement opportunities can be captured by focusing on pilot districts with the highest emissions. The four districts of Nunukan, Kutai Kertanegara, Kutai Barat, and Kutai Timur account for 80 percent of the 18.5 MtCO2 potential abatement from implementing a zero burning policy. Nunukan's fires, for example, are largely concentrated in two areas of about 60,000 ha near to and on peatlands. One command post and six brigades could likely cover most of the district's fires. Whereas in Kutai Kertanegara, fires are spread across wide areas, likely raising costs above the provincial average. Within this district, fire prevention brigades should focus on the 700,000 ha of land that is mostly degraded peat and thus susceptible to fire and large emissions. In terms of abatement from rehabilitating abandoned peatlands, 80 percent of the potential abatement will come from the four districts of Nunukan, Kutai Kertanegara, Kutai Barat, and Bulungan. These potential pilot projects have been identified based on abatement potential; a finalized list of pilots would also need to assess criteria such as types of farmers in each area and community support.

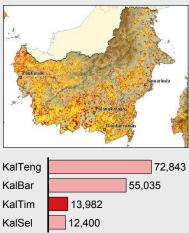

#### **GDP** Potential

There is an opportunity to increase the value added from agriculture by boosting yields, which could yield IDR 3.2 trillion in additional GDP by 2030. East Kalimantan's yields on major food crops, such as rice and cassava, are 60 percent below best practice yields in Java and Sumatra. This is partially due to the difference in soil quality: East Kalimantan lacks the rich volcanic soils of Sumatra for example. However, low yields are caused not only by poor soil conditions, but also from low access to inputs such as fertilizers, seeds, and farming equipment. Even compared to the yields across all of Indonesia, East Kalimantan's production is still 20 percent below average production (EXHIBIT 40). If East Kalimantan could raise its agricultural yields to the average yield level in Indonesia, it could increase the annual growth of its agricultural GDP from 3 percent to 6

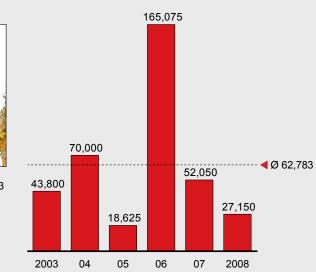

## Fires are of critical importance for East Kalimantan's emissions

## Zero burning policy must be tailored to different types of land

 Intact tropical forest is virtually fire-proof. Almost of all fires in East Kalimantan occur in logged over and degraded lands

## Strategy: No conversion

•Maintain intact forests and fully hydrated peatlands protects them against fires

Fire is a traditional and cheap land-clearing tool
It is also used to show cultivation to maintain/prove ownership

#### Strategy: Fire prevention

 Invest in alternative land clearing tools and training
 Remove regulatory incentives that allow fire clearing to prove active cultivation to retain concessions

Fires set to clear active lands spill over into abandoned lands
Degraded peatland and forests are very vulnerable to fire

#### Strategy: Fire fighting

•Create local community fire brigades in hot spots •Invest in wells and tools to fight peat fires requiring treatment below the surface

## Exhibit 38

## Nunukan's fires are quite concentrated, on the border of a major peatland and outside current timber concessions

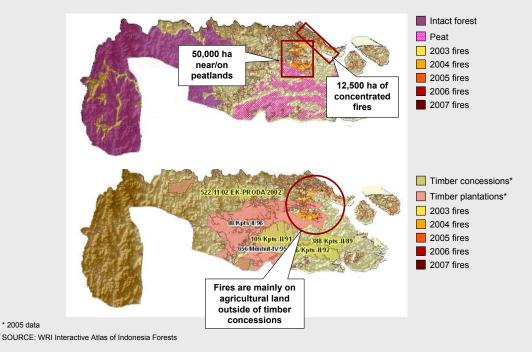

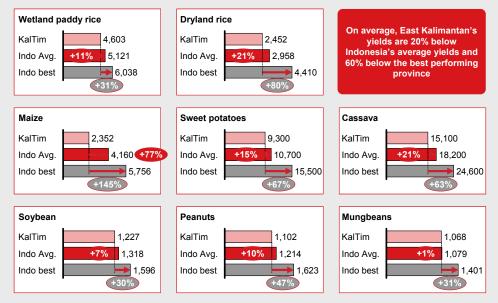

Exhibit 40

## East Kalimantan has the potential to raise crop yields by at least 20% and increase productivity in the agricultural sector

SOURCE: Team analysis

percent p.a. by 2030. This would result in an additional IDR 3.2 trillion of GDP in 2030 (EXHIBIT 41). Improving yields requires better seedlings, inputs, and farming practices, all of which will require substantial support to implement with many smallholders farmers on their lands. It will be important to raise yields sustainability and not by overuse of fertilizers alone, which could result in other environmental degradation.

### Expanding aquaculture and estate crops on degraded land will allow the agricultural

sector to expand and increase incomes for smallholders. There are over 50,000 ha of small plots and 400,000 hectares of mid-sized plots of degraded land that could be used for smallholder estate crops. A wide variety of estate crops can be grown in East Kalimantan, but a mixture should be used to balance the demands of capital, return, and jobs (EXHIBIT 42, EXHIBIT 43,). While coconut generates high revenues of IDR 42 million per ha, it also requires a high capital investment in the early years of IDR 128 million per ha. Cocoa, in contrast, yields only IDR 20 million per ha, but requires much less investment at IDR 20 million per ha. Seaweed generates almost twice as many jobs per ha as rubber, but requires twenty times the initial investment. Seaweed also has the guickest payback of only two and a half years.

### **Required Policies and Institutions**

#### Implementing these initiatives will require changes in how farmers manage their lands.

These farmers will require significant support to make these shifts. Efforts to raise productivity and reduce emissions from ending fires should be done hand-in-hand, so farmers see both direct benefits as well as the intangible value of reducing emissions. The traditional approach to working with farmers has been through public research and government extension workers; however, funding for these has decreased since decentralization and are not always the most effective option. We aim to increase the private sector's contribution to improving farmers' livelihoods and practices in addition to government support. In addition, working with all of East Kalimantan's smallholders directly is too large a task and requires some form of aggregation to work with

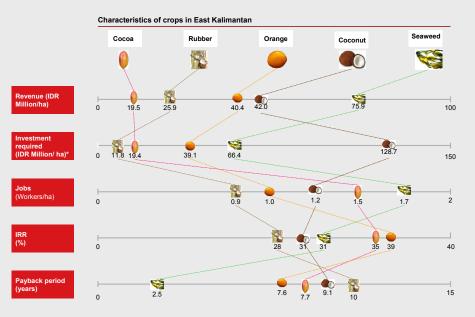

## New pockets of environmentally sustainable growth can be developed from agriculture and aquaculture on already degraded land

SOURCE: East Kalimantan Investment Board

### Exhibit 43

## A wide variety of estate crops with different characteristics and returns can be developed in East Kalimantan

Source: Regional Investment and Permittance Board of East Kalimantan Province

farmers . We have identified several important enablers for the agricultural sector including spatial planning, technology, farmer productivity, market access, and MRV. An agricultural transformation depends on all parts of the agricultural system working together; while each element can improve the agricultural sector's production and abatement, a sustainable solution requires all elements working together.

In order to support the growth of the agricultural sector, spatial planning should focus on identifying several 'breadbasket' areas. A breadbasket strategy aims at a breakthrough in food production in certain defined geographic areas. Breadbaskets are defined as agricultural areas with potentially high productivity for specific food crops, good market access potential, and relatively high rural population density. In addition, to support East Kalimantan's goal to reduce CO2e emissions, these breadbaskets should also be located in areas with degraded lands or grasslands to prevent further deforestation. By identifying breadbasket regions, agricultural expansion can be focused in the areas with highest potential as well as lowest emissions.

Nucleus-Plasma schemes (*Perkebunan Inti Rakyat*) are an important tool to raise yields of smallholder estate crops located near major plantations. Nucleus-plasma programs have been developed for palm oil plantations but could be expanded to other, high-value estate crops. The programs work by having plantation companies develop palm oil plots for smallholders in a 'plasma' area around their own plantation 'nucleus'. The management of the plasma area is run by a cooperative of the smallholders, which typically contracts technical functions back to the nucleus plantation company, thus growers often work as laborers on their plots. The smallholders receive seedlings, inputs such as fertilizers, and often a guaranteed price for their produce. These schemes have worked in East Kalimantan, and plasma smallholders have yields twice as high as independent palm oil smallholders. But the plasma schemes do have weaknesses as they can interfere with traditional community management of lands (*adat*) as well as change traditional land ownership patterns. Plasma schemes could be expanded to other high-value estate crops; for less profitable estate crops, government subsidies may be needed to get private sector support for such programs.

**Capability building can be achieved by creating a limited number of aggregation units operated by private local change agents** (e.g., local entrepreneurs and farmers as well as small warehouse operators on the post-harvest side) whom government, donors, input/off-take companies, and banks can work with and who in turn will aggregate and extend support to lead farmers and or farmer groups and individual smallholders on the production side. One option is to develop Agriculture Centers that will perform three types of activities: (i) offer off-take from farmer groups; (ii) provide inputs on credit; and (iii) provide services (e.g., tractor services, storage). Each Agriculture Center should have a large warehouse facility. International examples suggest it could serve farmers within a 20 km radius and work with about 200 to 300 lead farmers who would in turn aggregate about around 5,000 smallholders overall. These centers should be placed in agricultural breadbasket areas with sufficiently dense smallholder populations; based on current agricultural lands, number of smallholders, and infrastructure or market access, potential pilots could be in Kutai Kertanegara, Kutai Timur, and Penajam Paser Utara.

Extension services are still an important government program to supporting

**smallholders, particularly in isolated regions.** Private sector cooperation with farmers is often limited to those with high-value estate crops who are located in the lowlands near plantations and processing facilities. Thus, government extension workers are still important, particularly to provide access to credit, seeds, and technology to smallholders growing food crops and located in the more remote interior of East Kalimantan. Both the budget and number of extension service workers has fallen in Indonesia; today Indonesia has roughly 6 extension service workers per 10,000 farmers, compared to China, which has a ratio of 16 per 10,000. Moving to China's benchmark, East Kalimantan would need an additional 200 extension workers.

**Real-time and publicly available MRV systems are needed to help communities fight fires.** While the zero burningpolicies will help with fire prevention, inevitably some man-made fires will continue, and the community fire brigades will need to focus on extinguishing them. While watchtowers are an effective local means of monitoring, satellite detectors can identify remote fires or larger fires that will require support from the district and province to help suppress. There are already existing tools, such as the online IndoFire service, which are publicly available and can be used to support this monitoring.

### **COAL SECTOR**

**Coal mining has long been a source of tension in development plans.** Coal's value attracts substantial investment to East Kalimantan, and it provides significant tax revenues and contributes to GDP. Yet, coal mining provides few jobs compared to labor-intensive manufacturing or agriculture. If done poorly, mining can leave huge environmental consequences. Still, coal is a central part of East Kalimantan's economy and will remain so for decades. This strategy aims to improve its efficiency and seek measures to minimize its destructive impacts.

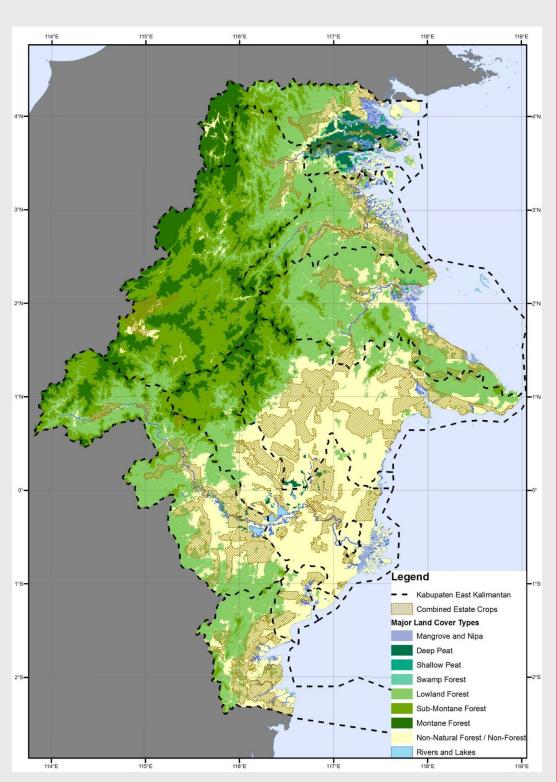

## **Current Context**

**East Kalimantan has several mineral resources, but coal mining dominates production.** While there remain an estimated 50 million tons of gold and silver, there has been very limited gold and silver production since the closure of the PT KEM mine in 2004. East Kalimantan has substantial coal reserves, estimated to be 3.6 billion tons, equal to 19 percent of Indonesia's total. Thus, virtually all mining today is for coal. The majority of East Kalimantan's coal is low in sulfur and ranges from low- to high-calorie (43 percent of reserves are within 6,100–7,100 CV range), which means East Kalimantan coal can be exported to both steel mills (which require high-calorie coal) as well as power plants.

**Coal mining is a significant driver of East Kalimantan's economy.** From 2000 to 2008, coal production grew rapidly by 15 percent p.a., raising its contribution to total GDP from 8 percent to 20 percent. Production has already reached 119 million tons and some infrastructure, such as ports, are reaching their limits. Going forward, growth in coal production is expected to slow to 5 percent, as infrastructure constraints and concession limits are reached, in line with Indonesia's average. (Box 4 discusses concession types.) At this rate, by 2030, the coal mining sector will account for a significant 31 percent share of the provincial real GDP.

**Coal mining in East Kalimantan contributes significant emissions, mainly through its associated deforestation, which are estimated to be 27 MtCO2e in 2010.** These emissions are equivalent to 11 percent of East Kalimantan's total emissions. Most emissions from coal mining are due to deforestation to open up areas for mining exploration and production, not the mining processes themselves. As each hectare of deforested land emits over 800 tons of CO2e, the deforestation due to mine opening accounts for 68 percent of the emissions from the coal sector, while the mining process itself (such as digging, crushing, and transport) contributed only 21 percent of total emissions. The remaining 11 percent of emissions comes from methane that is released from the coal seam as it is mined. As the coal sector is growing, emissions will likely grow by 2 percent p.a. and reach 41 MtCO2e by 2030, equivalent to 12 percent of the province's total emissions.

**Deforestation is high as most miners use open pit mining, which strips the surface of the concession.** Underground mining could avoid much of this deforestation, but it is unfeasible in East Kalimantan. Virtually all coal reserves in East Kalimantan are shallow, making underground mining technically unfeasible. Furthermore, mining in East Kalimantan is dominated by small companies, which lack the sophisticated equipment, knowledge, and funding to implement underground mining, which has much greater safety risks. Of 301 coal mining companies in East Kalimantan, only 2 have employed underground mining, i.e., Kitadin and Fajar Bumi Sakti.

## Many mining operations are located within the natural forests

## Exhibit 44

### Box 4

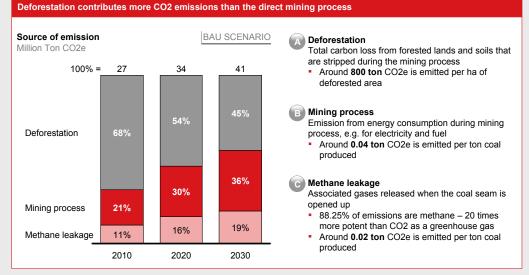

## **PKP2Bs**, **KPs**, and **IUPs**

Currently, there are two main types of coal concession in East Kalimantan, i.e., PKP2B (Perjanjian Karya Pengusahaan Pertambangan Batubara - Working Contract of Coal Mining Business) and KP (Kuasa Pertambangan – Mining Right). There are several differences between the PKP2Bs and KPs, however the key differences are their legal status and sizes. PKP2Bs are contracts between the central Government of Indonesia and relatively bigger mining companies. The average size of a PKP2B production concession is around 28,000 ha. PKP2Bs pay land rent and a 'production share' to the central government. On the other hand, KPs are permits awarded by local government to the relatively smaller mining companies. The average size of a KP production concession is around 1,000 ha. KPs pay land rent and a 'production royalty' to the local government.

Both PKP2B and KP are legal products prior to the new mining law, the UU No 4 Year 1999, which was actually issued in 2010. As per the new mining law, the Government of Indonesia now issues only IUP (Izin Usaha Pertambangan - Mining Business Permit). IUPs are analogous to KPs from the perspective of size (a maximum of 15,000 ha for production and 50,000 ha for exploration), status (a permit instead of contract), and financial obligations to governments (profit sharing). Yet, unlike the KPs, IUPs are to be awarded based on transparent tender process. Going forward, all new licenses will be IUPs. The law requires all existing KPs to be converted into IUPs by 2011. PKP2B contracts issued prior to the New Mining Law remain valid until their original contract expires.

### Exhibit 45

## Most emissions from the coal sector are due to deforestation to open the mining operation, not the process of mining

The model assumes no new exploration permits would issued beyond year 2008, thus all new production permits would come from existing exploration

Conversion rate: 90% of PKP2B exploration permits based on (1) ratio between average size of production and exploration concession and verified with (2) ratio of max area allowed during production and exploration phase; 33% of KP exploration permits based on (1) ratio between average size of production and exploration and exploration phase; 33% of KP exploration permits based on (1) ratio between average size of production and exploration explorat

SOURCE: Indonesia Abatement Cost Curve; Interviews; Simulation; Team analysis

Unlike timber or oil palm plantations, only a portion of a mining concession is deforested. Initial mining concessions start with exploration or feasibility study permits. For large miners, these concessions typically shrink by 60 to 75 percent as they move to production concessions; this is the result of exploration identifying the actual areas with commercially recoverable coal. In addition, a land rent is charged based on the size of the production concession, which encourages companies to seek the minimum size required. The average production concession for a large miner is 28,000 ha; of this, typically 20 percent of the area is disturbed, meaning that the earth is dug up and all vegetation on the surface is destroyed. The average size of a production concession for small miners is just 1,000 ha. Typically 75 percent of this small area is disturbed. (See Box 5 for more about being a KP miner.) The small companies have a higher deforestation rate for two reasons. First, they have far smaller areas than big companies; therefore the proportion of forested land they clear is bigger. Second, the small companies have less sophisticated exploration equipment; therefore they are less targeted and systematic in clearing the forests. The amount of deforestation depends on the whether the disturbed land originally contained forests or already degraded lands.

## Story of a KP Miner

Small miners face many challenges across the value chain in doing coal business in East Kalimantan. The challenges begin when the small miners apply for mining permits. Lack of transparency and lengthy bureaucracy of the application process create situations that are conducive for covert "transactions". Many small miners complained about the "transactions" which are, in many cases, costly, uncertain, and risky.

Once the mining permit is obtained, the next challenge is securing land access. The small miners need to compensate the local communities who live on top of the mining deposit or convince the HPH companies who hold logging licenses for the area to allow them to access the land. The small miners also need to tackle the so-called land mafias and land speculators by themselves.

The challenges do not end after land access has been secured. During the mining operation, the small miners must still manage the local mafias. These local mafias sometimes disguise themselves as legitimate stakeholders: members of local communities that are disturbed by mining operation, NGOs which fight for the local communities, or even as government officials that come to collect some kind mining retribution (lack of clear regulation allows this to happen). Furthermore, theft is common during the transportation of coal from the site to the port (small miners do not build their own ports or roads, but utilize the publicly available roads and ports). At certain locations, thieves come and hop on to the coal truck or coal barge, take whatever they can, and then hop off.

Lack of infrastructure also causes problems for the small miners. When their coal arrives at a port, the small miners must wait for their turn to ship their coal. Many times at certain ports, when the water level is too low and no barge can come in, the waiting time can be very long.

All of the above challenges – combined with their small area under license and lack of equipment and knowhow – lead to low margins for the small miners. To survive, the small miners then try to find ways to cut costs, which often results in skimping on proper land reclamation and rehabilitation.

**Going forward, the deforestation rate will likely increase as new production concessions are increasingly likely to be awarded to small companies.** In 2008, of the 1 million ha of licensed production concessions, around 192,000 ha have been deforested. Although small companies hold only 28 percent of the total area of production concessions, they account for 61 percent of the deforestation area. There are currently an additional 3 million ha worth of coal exploration licenses in East Kalimantan; given historical patterns, these would translate into an additional 1 million ha of production concessions by 2030, of which around 564,000 ha would be deforested. This implies an average deforestation rate of 56 percent of the total production area. The higher deforestation rate

## Box 5

predicted compared with the historical rate is because smaller coal mining companies will account for a higher share of future production based on the current pipeline of concessions.

### **Abatement Potential**

Four abatement initiatives have been identified which could abate 50 percent of the coal sector's total emissions. As deforestation is the largest source of emissions, the natural target for an abatement initiative is to stop deforestation; however, there are few good options to do this. Underground mining avoids large scale deforestation but it's infeasible in East Kalimantan. Unlike palm oil or timber, coal concessions can not be swapped to degraded lands. Coal reserves are located where they are located, regardless of the forest cover above. Stopping all mining on forest lands without outside compensation would result in significant loss of GDP.

There is illegal mining in protected forest areas, and this should be stopped. It would reduce CO2e emissions by 27 percent to 11.3 MtCO2e. Next, efforts should focus on reducing emissions from the mining activities themselves. An increase in operational efficiency levels would reduce emissions by 2.6 MtCO2e. Reducing methane release could result in 4.8 MtCO2e emission reduction. Finally, the last strategy is to reverse deforestation emissions post mining. The enforcement of proper post-mining reclamation would save a further 2.01 MtCO2e. It is important to stress that avoiding unnecessary or poorly planned deforestation is a far more important abatement lever than enforcing proper reclamation of forests after mining concessions expire. Enforcing reclamation regulations is certainly necessary, but the new trees will need 80 to 100 years to restore the original area as a net carbon sink.

#### Exhibit 46

#### ESTIMATE Four abatement levers have been identified that could save up to 50% of East Kalimantan's total emissions

Source of emissions	Abatement levers	Description	Emission reduction Mt, 2030	% of 2030 emission
Deforest- ation	Stop illegal mining	<ul> <li>Survey all forested lands, check licenses held by mining companies, and stop the operation if illegal</li> </ul>	11.32 <sup>1</sup>	(27%)
	2 Enforce proper post- mining reclamation	<ul> <li>Closely monitor mining companies</li> <li>Use special reclamation contractors</li> <li>Restructure the reclamation bond</li> </ul>	2.01 <sup>2</sup>	(5%)
Mining process	Encourage process efficiency	<ul> <li>Encourage operation efficiency</li> </ul>	2.56 <sup>3</sup>	(6%)
Methane release	Minimize methane release	<ul> <li>Reduce methane leakage by requiring methane flaring or utilization</li> </ul>	4.774	(12%)
		Total emission reduction =	20.66	(50%)

1 Assuming 90% of existing and future production concessions located in: Hutan Lindung, Cagar Alam, Hutan Penelitian, Taman Nasional, and Hutan Raya are illegal (based on existing PKP2B rate) 2 Assuming 100% reclamation rate is possible through enforcement

Assuming 20% emission reduction could be gained from mining operation efficiency (expert estimate adjusted with the fact that majority of miners in East Kalimantan are small players) 4 Assuming 70% of methane release can be stopped (expert estimate)

SOURCE: Interviews; Simulation; Team analysis

Stopping illegal mining in protected forest areas would see a 27 percent reduction equivalent to 11.3 MtCO2e. Vast areas of coal concessions are located in forest areas, some even within the protected forest estates. By some estimates, as much as 90 percent of the

exploration and production concessions located within protected areas are illegal.<sup>18</sup> An effective abatement strategy would require that East Kalimantan surveys all forested lands and checks the licenses of all mining companies within the forested lands The estimated cost to implement this initiative, in present value and excluding the opportunity cost from illegal mining, is around USD 0.01 to 0.02 per tCO2e p.a. by 2030. Box 6 discusses mining infrastructure and deforestation.

#### **Mining Infrastructure and Deforestation**

If not managed well mining infrastructure could lead to further deforestation. In order to access the coal deposits in the middle of forests, many big miners in East Kalimantan build roads across the forest areas. However, the availability of roads allows settlers to encroach on the forest. It is not uncommon that the settlers also clear trees and build permanent structures along the roadsides. Small miners, unlike the big ones, are generally unable to afford their own infrastructure. Therefore, they leverage the existing public roads, HPH roads, or rivers. The use of existing HPH roads can actually prevent further deforestation, as the roads are typically managed by the HPH companies that have strong interests to control their logging area and prevent encroachment from the settlers. Going forward, big miners need to leverage the HPH roads or alternatively build railways instead of roads to minimize settlements along roadsides.

To accommodate the coal mining workers, many big miners also build small encampments near the site in the midst of the forest. While the mine is operating, the encampments grow bigger as many local traders come to establish their businesses. Some even bring their families and build houses around the encampments. When these mining encampments have grown large enough, they can apply to be formal villages (desa) or even sub-districts (kecamatan). If approved, then the encampments will become permanent villages and will be entitled to some development funding. The growing sub-districts then increase their pressure on the forest areas. Going forward, East Kalimantan needs to encourage the big miners to prevent the unplanned growth of encampments.

**Minimizing methane release could capture 4.77 MtCO2e of abatement.** Reducing the release of methane into the atmosphere is the second largest abatement lever after deforestation. Methane is 20 times more potent than CO2 as a greenhouse gas, and coal seams in East Kalimantan have high concentrations of methane, 1.46 m3 per ton of coal (around 88 percent of total gas concentration in coal). As coal mining in East Kalimantan is dominated by open pit mining, methane is released from seams when miners remove the earth above the deposit (overburden). Additional methane trapped in rock pores is released during the crushing and milling process. Yet, no measures to mitigate the release of methane are currently in place in East Kalimantan. Existing mining legislation is not explicit enough in prohibiting methane releases. Moreover, the commercial utilization of methane gas is hindered by the current regulations for coal-bed methane, which requires coal miners to follow a lengthy process if they want to flare<sup>19</sup> or use the methane.

We have identified a number of recommended steps to help reduce methane release: petition the Ministry of Energy and Mineral Resources to simplify the requirements for CBM; pass new regulations requiring methane capture in mining operations; provide technical support to miners that apply for Clean Development Mechanism funding; and launch a new mining monitoring

#### Box 6

<sup>18</sup> Not all mining operations located within protected zones are illegal. Within the protected zones, there are many different forest types. To simplify from the mining point of view, there are two main categories: 1) Conservation forests (e.g., Cagar Alam, Suaka Margasatwa) – strictly no mining unless the mining right or contract had been issued prior to the new forestry law, UU No 41 Year 1999; 2) Protection forests (e.g., Hutan Lindung) – surface mining is prohibited, underground mining is allowed with prior approval from the Minister of Forestry, unless the mining right or contract had been issued prior to the new forestry law, UU No 41 Year 1999; 2) No 41 Year 1999.

<sup>19</sup> Flaring converts the methane to CO2, and therefore it is more environmentally friendly than having methane, which is a 20 times more potent greenhouse gas than CO2, be released to the atmosphere directly.

team to check on methane release at mining sites. The cost, in present value, required to reduce emissions by reducing methane release from coal mines is around negative USD 2 to 3 per tCO2e p.a. by 2030.

**Encouraging operational efficiency could capture a reduction of 2.56 MtCO2e.** Both emissions from the mining process and the profitability of coal mining are mainly driven by the consumption of fuel and electricity. Expert interviews suggest that East Kalimantan could reduce energy consumption (and hence emissions and costs) by around 20 percent through operational efficiency improvements. One step the provincial government could consider is training a new provincial mining monitoring team to be able to recommend operational improvements during their site visits. The members of the provincial mining monitoring team then will also assess efficiency and suggest improvements to the mining companies. Examples of operational efficiency initiatives include: reduce idle time of shovels, improve control of transport equipment, improve fill factor for shovels, improve haul road, optimize truck dispatch, and improve fuel monitoring and maintenance. Which initiatives are appropriate is dependent on the result of site assessment by the provincial mining monitoring team. The cost, in present value, to implement all these steps to improve operational efficiency is estimated at negative USD 4 to 6 per tCO2e p.a. by 2030.

**Enforcing proper post-mining reclamation would save 2.01 MtCO2e.** Although the environmental impact of open pit mining is inevitable, the damage can be minimized through implementation of best practices for reclamation. In violation of existing regulations, many miners in East Kalimantan, especially the smaller ones, do not implement proper reclamation practices. Interviews with industry participants and mining sector analysts suggest that around 20 percent of big companies and 75 percent of small companies do not implement proper reclamation. Their reasons vary. Many smaller miners don't have the capital to finance reclamation activities. (An upfront reclamation guarantee fund does exist, however in many cases it is not adequate to cover the full cost of reclamation or it is simply not collected properly.) Some miners do not implement proper reclamation because they know that government has limited resources to monitor and control them, and therefore the consequences of violating the reclamation provisions are limited. Box 7 discusses the economic opportunity of post mining reclamation.

Three initiatives to enforce proper post-mining reclamation have been identified. First, to address the problem of a lack of skills and knowhow, certified reclamation contractors can be used. Miners with insufficient capability to do reclamation could contract one of the contractors on a recommended shortlist. Second, to address the lack of financial resources, the reclamation guarantee fund system can be adjusted. Instead of requiring applicants for mining permits to pay small upfront guarantees, East Kalimantan can require them to pay the full reclamation costs in advance to any certified reclamation contractor in East Kalimantan and attach the reclamation contract to their permit application. Then, the East Kalimantan government will only need to hold the certified reclamation contractors, instead of the applicants, responsible for implementing proper reclamation. It will be easier for East Kalimantan to manage a few certified reclamation contractors as opposed to thousands of mining companies. Third, to address the issue of lack of enforcement, East Kalimantan could establish a new mine monitoring unit with sufficient resources and regulatory authority.

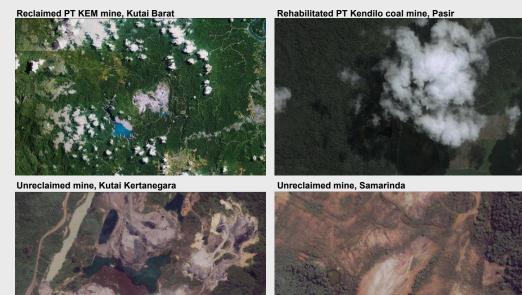

To ensure successful reclamation (1) rehabilitation programs should be an integral part of operations from the commencement of mining; (2) lands should be rehabilitated immediately upon the closure of each mining pit; and (3) an extensive consultation process with community stakeholders should start a few years before the closure of a mine. There are several successful reclamation examples in East Kalimantan such as the Petangis coal mine in Paser rehabilitated by PT Kendilo and the PT KEM gold mine in Kutai Barat. The Petangis mine rehabilitated its post mining lands into an eco-tourism park, for which it received the Gold Flag environmental award from the Province of East Kalimantan. To enforce proper reclamation, East Kalimantan will need to add 65 qualified personnel to a provincial mine monitoring team. The estimated total cost, in present value, for these steps to enforce reclamation would be around USD 6 to 22 per tCO2e p.a. by 2030.

# The Economic Opportunity of Post Mining Reclamation and Rehabilitation

While reclamation and rehabilitation is seen as a cost for private mining companies, it is actually an economic opportunity for East Kalimantan overall. Without proper reclamation, soils in mining concessions become degraded and cannot be used for other economic purposes. Another benefit, then, of strictly enforcing post-mining rehabilitation regulations is that it allows other sectors to use the mining concession area after the concession period has expired. Properly reclaimed lands ensure the continued viability of the soil, which could therefore be used for forestry, palm oil, or agriculture. This would result in decreased pressure on the primary forests, higher carbon sequestration than otherwise would be the case, and more job creation.

Based on existing reclamation practices, by 2030 under the business-as-usual scenario, only around 137,000 ha of mined lands will become available for either forestry, palm oil, agriculture, or other uses after mining concessions lapse. However, if existing reclamation regulations were properly enforced, an additional 289,000 ha of reclaimed lands would become available for other economic purposes by 2030.

#### **Pilot Projects**

#### Potential pilots for coal initiatives have been identified in Kutai Kertanegara, Kutai

**Barat, and Kutai Timur.** As 75 percent of miners with KP permits and 64 percent of KP coal concession areas are concentrated in these three districts, the highest emissions and greatest abatement potential are also there. Pilot projects in these three Kutai districts could capture almost 75 percent of the total abatement potential from the coal sector (EXHIBIT 48). Other criteria to be used for selecting the final pilot projects would include: support from districts, support from mining companies, and the availability of biodiversity and HCVF at risk.

#### **GDP** Potential

Improving the productivity of coal miners could increase the sector's contribution to GDP in the order of IDR 10 trillion by 2030. In a business-as-usual scenario, 88 percent of the new production concession areas would be dominated by small companies. However, most small companies are far less productive than the big ones due to differences in mining tools, production equipment, knowhow, and extraction methodology. Currently, the average productivity of small miners is 59 tons per ha p.a., far lower than the average productivity of the big companies of 144 tons per ha p.a. With over 1,200 small miners, it is difficult to support them all with financing, technology, and training to increase production. The natural response of the market would be consolidation of the small miners into larger, more efficient mines and companies; yet, this has been slow to occur in East Kalimantan. Thus, the best identified option is to improve productivity by better screening of new miners and issuing production permits only to companies with sufficient technical capabilities. The provincial mining monitoring team can help districts assess the technical capabilities of the applicants and any contractors they intend to employ.<sup>20</sup> Based on those assessments, the mining monitoring team would then recommend to the districts whether to reject or accept the application.

Other potential initiatives to increase GDP from coal have been rejected as they are too

**carbon-intensive.** Beyond improving the productivity of coal extraction once a site has already been deforested, the options for increasing the economic value added from coal require moving downstream and utilizing the coal itself, which creates more emissions. There is downstream potential for coal-to-liquid processing to produce diesel, but this produces far more CO2e than conventional oil refining. The coal could be burned to produce power, potentially for export for other parts of Kalimantan or Malaysia, or used to power energy-intensive industries such as steel, aluminum, and cement. Yet, all these options do not move the coal sector to less-carbon intensive

<sup>20</sup> The mining contractors will need to be rigorously inspected as well

activities. There may be some opportunities to use blending with higher quality coals to gain the premium price for steel-quality coal and thus earn a higher return, but this type of blending is typically done by end-users and any margins are captured by them.

#### **Required Policies and Institutions**

A strong mining monitoring team is crucial for the success of the abatement and GDP improvement initiatives. The monitoring team would play many important roles in the implementation of abatement and GDP improvement initiatives.

East Kalimantan, today, already has personnel to monitor the mining companies, i.e., the special mining police or mining inspectors *(polsus pertambangan or inspektur tambang)*. However, the monitoring is not effective due to several challenges. One is the number of personnel. Experts estimate that the minimum ratio between the number of personnel and number of operating mining companies for effective monitoring should be 1:10. Currently, the ratio in East Kalimantan is 1:150 with only two part-time members of special mining police to oversee 301 mining companies in production. The estimated number of mining companies that will be operating by 2030 is around 620 companies. Therefore, East Kalimantan will need a total of 62 full-time personnel.

The second challenge is a limited budget to conduct site visits. Ideally, each mining company needs to be visited every six months (this means 1,240 visits per year for 620 companies). However, current budget only allows the monitoring personnel to visit one company per year. Furthermore, the current personnel has limited authority to do unannounced site inspections. They need to report to the mining company first before they come, and then take a guided tour led by the mining company.

Another challenge is the quality of personnel. Ideally, the members of the mine monitoring team should be mining experts. Therefore, the members of the provincial mining monitoring team should have the following qualifications: (1) educational background related to mining; (2) relevant work

experience in the industry, e.g., ex-manager of a good mining company; and (3) training in site inspection.

In summary, it is very important for the provincial monitoring team to have:

- Sufficient authority and power to undertake all of its responsibilities
- Clarity of roles and responsibilities between the team members and the provincial and district mining authorities (dinas)
- Sufficient expertise and knowledge
- Highest possible integrity of people and processes, and world-class governance processes

#### Exhibit 50

## Almost all of the abatement levers could be implemented through a provincial mine monitoring team

Initiatives		Can a mine moni- toring team help?	What role can the mine monitoring team play?
GDP improvement	Implement stricter review of license applications	Yes	<ul> <li>As the provincial expert body who reviews the application<sup>1</sup></li> <li>Quality of AMDAL and mining technical plans</li> <li>Company background check</li> </ul>
Abatement	2 Stop illegal mining	Yes	As the surveyor/inspector who can survey the forested lands and check the company's licenses
	3 Enforce proper post- mining reclamation	Yes	As the inspector who visits the sites and monitors closely
	Encourage process efficiency	Yes	As the expert who visits the sites, observes and diagnoses the mining practices and recommended improvement initiatives
	Minimize methane release	Yes	As the inspector who visits the sites and monitors closely; Also as a facilitator that helps companies to apply for CDM projects

## OIL AND GAS SECTOR

#### The oil and gas sector has been a fundamental driver of East Kalimantan's economy for

**decades.** Onshore fields have been producing oil in East Kalimantan since before Independence; in the 1970s, the sector developed further with the discovery of massive offshore gas fields. Recently, East Kalimantan has been pioneering Indonesia's development of coal-bed methane. East Kalimantan's production has been important nationally; it accounted for 42 percent of national upstream gas production and 90 percent of national LNG production in 2008. Yet, the sector is currently in decline with oil and gas production falling 1 percent p.a. since 2000. Thus, in a business-as-usual scenario, emissions from the oil and gas sector will decline naturally. In the other sectors discussed in this report, we have first evaluated options for reducing the current carbon footprint of the sector before considering how to expand the sector with new higher value-adding and lower carbon-emitting activities. Given the expected decline of oil and gas sector going forward, we have switched the order here and first explore how to reverse the sector's decline. We then turn to the topic of how to reduce emissions from a larger, revitalized industry.

#### **Current Context**

# The oil and gas sector contributes almost half of East Kalimantan's GDP but has been declining at an accelerating rate, 1 percent p.a. since 2000 and 3 percent p.a. since 2005. The majority of East Kalimantan's oil and gas fields are already mature and production volumes are declining 3 percent p.a. The impact on the province's GDP of this decline is further amplified by the subsequent drop in downstream gas processing. While the Balikpapan refinery continues to run at 99 percent of its maximum capacity by importing crude oil supplies, the Bontang LNG production facility continues to decline and in 2008 was operating at 80 percent capacity, as it must rely on the declining gas feed from nearby upstream fields. If these trends continue, there will be a significant drop of GDP contribution from oil and gas to East Kalimantan, from IDR 47.2 trillion in 2008 to IDR 31.6 trillion in 2030. This declining role of the oil and gas sector is likely to increase East Kalimantan's dependence on other, more carbon-intensive sectors such as agriculture, palm oil, and coal mining to secure its future growth.

In 2010, the oil and gas sector produced approximately 17.8 MtCO2e from both its upstream and downstream activities. Upstream oil and gas production produced 6.9 MtCO2e; 23 percent of this stemmed from the energy used for the drilling and operating of the production fields. The remaining 77 percent was due to flaring. Flaring occurs most commonly in oil fields where associated gas is produced along with oil from the fields; this gas is separated from the oil at surface facilities and then flared (burned) if the operators do not use it for internal purposes or sell to others. Flaring can also occur at gas fields if production exceeds the field's processing capacity as well as at downstream processing facilities. An estimated 3.3 MtCO2e are generated from the Balikpapan refinery due its energy needs and processing of oil. The Bontang LNG plants produces an estimated 7.6 MtCO2e from its high energy needs to process, cool, pressurize, and liquefy the natural gas.

#### **GDP** Potential

We have identified three GDP improvement initiatives that could reverse the decline of East Kalimantan's oil and gas sector and increase GDP by an additional IDR 64.3 trillion by 2030. These initiatives are accelerating upstream exploration (2030 GDP increase of IDR 4.7 trillion), developing coal-bed methane (CBM) fields (IDR 24.3 trillion), and building new downstream gas facilities once the new CBM stream is online (IDR 3.63 trillion) (EXHIBIT 51).

Accelerating upstream exploration would see an increase of 2030 real GDP by IDR 4.7 trillion. East Kalimantan's oil and gas resources have been largely exploited, but there remains some potential for new exploration and production, particularly in gas. East Kalimantan's oil and gas deposits are found in two main basins, the Kutai Basin and Tarakan Basin. The Kutai Basin, for example, still holds estimated reserves of 474 million barrels of oil and 20,663 billion cubic feet (bcf) of gas. Besides in-field exploration, the United States Geological Survey (USGS) routinely estimates how much resources are "yet-to-find" and could be expected from future exploration efforts in a basin. For the Kutai Basin, for example, there is an estimated 50 percent chance (F50) that at least 59.8 trillion cubic feet of gas could be discovered in fields of various sizes. Doubling current exploration efforts could yield new oil and gas production of 35 mbpd and 766 million cubic feet per day (mmcfd) by 2030. Yet, this is insufficient to fully offset the decline in existing mature fields. Accelerated exploration can merely slow the decline in oil production from 8 percent p.a. to 3 percent and the decline in gas production from 2 percent p.a. to almost 0 percent.

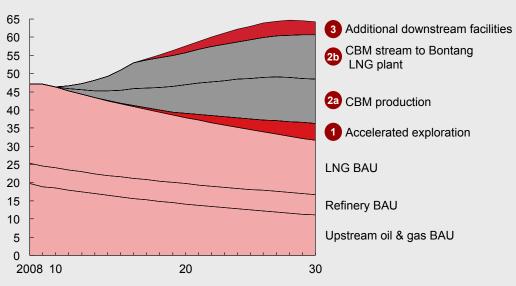

**Coal-bed methane (CBM) is one of the biggest opportunities for East Kalimantan and could increase 2030 GDP by IDR 24.3 trillion.** Coal-bed methane is a recent development that allows methane (natural gas) trapped in coal seams to be located, drilled, and sold to conventional gas buyers. East Kalimantan has CBM resources of 109 trillion standard cubic feet (tscf), almost a quarter of Indonesia's CBM potential (EXHIBIT 53). The current CBM explorations are focused on four exploration blocks within the Kutai Basin that are close to the Bontang LNG plant; they were

# Three GDP improvement initiatives could reverse the decline to lift 2030 real GDP to IDR 64.25 trillion

#### Real GDP

#### Exhibit 52

# East Kalimantan's oil & gas resources have been largely exploited but there remains some potential for exploration, particularly in gas

SOURCE: WoodMackenzie, USGS, team analysis

granted in 2008–2009 and contain 12.7 tscf. Assuming continued auctions of CBM blocks<sup>21</sup> to 2030 (but at a more conservative pace and size) that would cover at least 60 percent of current resources, East Kalimantan could produce an additional 2,500 mmcfd of CBM gas production by 2030.

This new stream of coal-bed methane would double business-as-usual gas production by 2030 from 2,200 mmcfd to 4,700 mmcfd. Furthermore, this new supply of gas from CBM could be used to raise LNG production at Bontang LNG plant to its historical utilization rate of 92 percent, despite the declining conventional gas feed. There should be ample markets for the additional LNG from Bontang, from the existing buyers in South Korea, Japan, and Taiwan as new markets such as China.

## East Kalimantan has CBM resources of 109 TSCF, almost a quarter of Indonesia's CBM potential

#### Building additional downstream gas processing facilities would result in a GDP increase

of IDR 3.6 trillion by 2030. Coal-bed methane should be fed to the Bontang LNG plant and PT Pupuk Kaltim fertilizer plant until the gas feed exceeds the maximum capacity of these plants. By 2017, the CBM gas feed would reach the maximum capacity of the Bontang LNG plant: 3.7 billion standard cubic feet per day (bscfd). By 2023, the excess CBM supply would reach 1.0 bscfd, enough to operate two additional LNG liquefaction and purification facilities (called LNG trains) and by 2030, three additional LNG trains. Building a new LNG train requires large capital investment and can require up to five years to complete; thus investors are typically reluctant unless they can be assured of sufficient long-term supplies. The decision whether to expand LNG trains based on CBM supplies would be made in the future and depend on the regulatory framework at the time, LNG prices, domestic demand, and certainty over supply. It may be easier to find investment for capital-intensive downstream facilities such as fertilizer and petrochemical complexes that use

Located in East Kal

Exhibit 53

<sup>21</sup> The four exploration blocks are Kutai West (5.1 tscf, explored by Newton Energy, Ephindo, and CBM Asia), Sanga-Sanga (4.0 tscf, explored by Vico, BP, and ENI), Kutai-Ephindo (3.1 tscf, explored by Ephindo), and Sanggata West (0.5 tscf, explored by Pertamina, Arrow, and Ephindo)

also natural gas as an input. We recognize that we will need to work with the national investment board and regulatory agencies to encourage new investment into CBM.

#### **Abatement Potential**

Emissions from the oil and gas sector are forecasted to fall naturally from 18.5 to 11.4 MtCO2e as oil and gas production declines under business as usual. Emissions from the Balikpapan refinery would remain constant as the plant continues to operate at capacity. Emissions from the upstream processes to produce oil and gas would decline as oil and gas production decreases. In addition, under business as usual, the emissions from flaring would decline in tandem with the decline of upstream oil production.

The revival of the oil and gas sector, through the implementation of the GDP improvement initiatives outlined above, would counteract the natural decline in emissions under business as usual. With the decline of oil and gas production, the total emissions of the oil and gas sector are estimated to naturally decline from 18.5 MtCO2e in 2008 to 11.4 MtCO2e in 2030. However, the GDP improvement initiatives above would see higher production of oil, conventional gas, CBM gas, and LNG, which would push total sector emissions to 26.3 MtCO2e by 2030.

Three abatement initiatives have been identified for the oil and gas sector that could reduce emissions by 2.8 MtCO2e, equal to 10 percent of the revived oil and gas sector's emissions. Implementation of a zero flaring program in East Kalimantan would result in emission abatement of 1.7 MtCO2e p.a. by 2030. The Ministry of Energy and Mineral Resources, under the Green Oil & Gas Industry Initiatives, has targeted Indonesia to reach zero flaring by 2025. East Kalimantan could be the first pilot province for this program and introduce a Kaltim Zero Flare program (Box 8). The total cost, in present value, of implementing this initiative would be USD 8 to 10 per tCO2e p.a. by 2030.

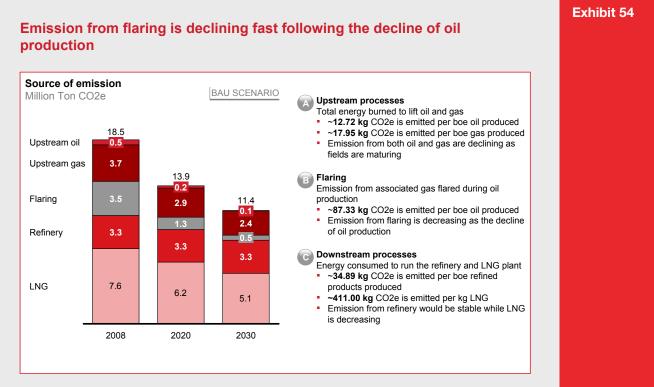

#### **Box 8** Zero Flaring is Possible and Could Be Cost Negative

It is possible to achieve the negative cost of zero flaring from a technical perspective. There are many viable options for utilizing associated gas from a field; the appropriate option depends on the amount of gas and the characteristics of the field. If the field is near existing gas infrastructure and pipelines, the associated gas can be sold commercially into the system (after investing in connecting pipelines) instead of flared. If there is no gas grid within an economical distance, excess gas can be sold to neighboring energy-intensive factories or local power plants. If this is not available or the amount of gas is small, then the excess gas can be used for power generators and compressors at the field site, replacing diesel fuel. The gas can also be reinjected into the reservoir itself to maintain pressure and production levels under the right circumstances.

In addition to the revenues and cost savings from the above options, there is the potential to receive CDM funding for flare reduction initiatives. At the Tambun and Pondok Tengah fields, up to 40 mmcfd of flared gas is utilized for power generation, and the estimated carbon reduction is around 0.4 MtCO2e p.a. Thus, zero flaring, in many cases, can be achieved at a negative cost.

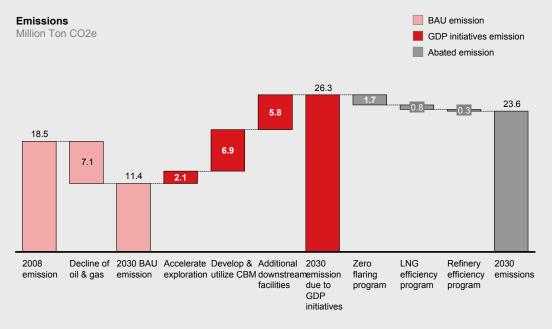

Implementation of an LNG plant operational improvement program, such as improved planning, would reduce emissions by 0.8 MtCO2e p.a. Improved planning can save fuel,

as plants can reduce unnecessary pressurization and depressurization by actively matching compression needs with natural gas demand. In addition, improved planning places emphasis on running compressors at their most efficient point, called the working point. The total cost, in present value, of implementing this initiative would be negative USD 19 to 28 per tCO2e p.a. by 2030, as the revenues and cost savings from improved planning outweigh the cost of equipment and investment.

# The revival of the oil and gas sector, through initiatives to improve GDP, would inevitably increase the 2030 BAU emission

SOURCE: Team analysis

Exhibit 55

**Implementation of a refinery operational efficiency program would reduce emissions by 0.3 MtCO2e.** The Balikpapan refinery can reduce its emissions by implementing efficiency measures that involve replacement, upgrades, or additions that do not alter the process flow of the refinery, e.g., waste heat recovery via heat integration and replacement of boilers, heaters, turbines, or motors. The total cost, in present value, of implementing this initiative would be negative USD 10 to 15 per tCO2e p.a. by 2030, as the revenues and cost savings from the refinery operational efficiency programs outweigh the cost of equipment and investment.

#### **Pilot Projects**

#### The pilot projects should be implemented in Kutai Kertanegara for zero flaring program, Bontang for LNG efficiency program, and Balikpapan for refinery efficiency program.

By 2030, Kutai Kertanegara, Balikpapan, and Bontang will account for 98 percent of the sector's emissions with 1.4 MtCO2e from flaring at Kutai Kertanegara, 15.0 MtCO2e from Bontang LNG, and 3.32 MtCO2e from Balikpapan refinery. These three districts will also account for 91 percent of the abatement potential by 2030. Kutai Kertanegara, with many fields, has high emissions from flaring that contribute almost 85 percent of East Kalimantan's flaring emissions. Satellite images detect more than 10 flare points in the district. By 2030, implementing a zero flaring program in Kutai Kertanegara could abate around 1.4 MtCO2e. Implementing operational efficiency programs at Bontang LNG plant will reduce 0.8 MtCO2e, and implementing energy efficiency programs at Balikpapan refinery will abate 0.3 MtCO2e.

#### **Required Policies and Institutions**

**To accelerate exploration, there are five challenges to be addressed** as reported by the industry: uncertainty of cost recovery regulations hinder private sector investment; contract sanctity is sometimes violated; unforeseen disputes with other agencies such as the tax office create additional costs; the overall taxation rate is not competitive with other exploration locations; and lack of security of assets and ownership rights causes uncertainty.

#### East Kalimantan should help the industry to address these exploration challenges

by: encouraging BP MIGAS to switch from a cost recovery focus to maximizing investment; encouraging BP MIGAS to quickly settle the Offshore Mahakam dispute in a transparent and credible manner; actively collecting feedback related to interference by other agencies from major companies and escalating it to national ministries; actively collecting feedback related to total tax rate from major companies and escalating it to national ministries; and creating a one-stop center with staff dedicated to the largest PSCs to facilitate access and ensure security.

## There are four regulatory issues that constrain the development of CBM: PSC regime, local procurement requirement, land access, and water management. The existing oil

and gas based PSC regime is not conducive for CBM development. Due to the cost recovery scheme, all well drilling, work programs, and budgets need to be approved beforehand by BP MIGAS. This is not suitable for the complex and long-term nature of CBM activities. For example, with the lengthy approval process of the current PSC regime, it could take up to one year for the approval of one well, yet CBM developments require hundreds of wells to be drilled. Similarly other approvals for work programs, budgets, and other items take a long time and are thus ill-suited to the phased development required for CBM. The existing PSC scheme also requires First Tranche Petroleum (FTP), a mechanism that allow the Government of Indonesia to claim upfront 20 percent of gross production regardless of whether the production volume will be sufficient to cover the total exploration and development of Indonesia, means higher risk for contractors. This is not conducive for CBM development that requires higher upfront investment. Countries like India and China offer better fiscal regimes to address the high upfront risk related to CBM development.

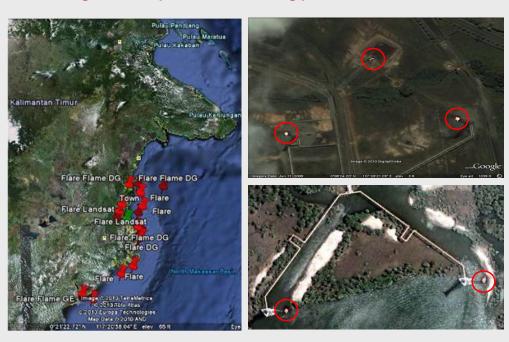

The requirement for local procurement hinders the development of CBM. Current regulations require operators to use local contractors and procure equipment locally. Non-local

procurement is only allowed with the approval of the Minister of Energy and Mineral Resources. However, as the CBM business is relatively new for Indonesia, no local equipment suppliers and contractors have yet built the skills to support large-scale CBM development projects. Existing procurement rules and local content requirements make it difficult for CBM operators to import necessary skills and equipment.

**Conflicts regarding access to land hinder the development of CBM.** Much of the land on top of CBM basins is likely to be already held by other parties, e.g., coal miners, oil and gas companies, oil palm plantations, or logging companies. Although Kepmen No 36/2008 has clarified the rules on CBM operators' rights and land access, i.e., CBM companies can negotiate with other parties for land access, it does not go far enough to resolve the lengthy negotiation process involved between the CBM operator and multiple parties and the price to be paid for land access.

Unclear regulations on water management, especially when the CBM fields are far from the sea or rivers, hinder the development of CBM. The dewatering processes during CBM development produce large streams of water that need to be properly diverted. However, current regulations are not clear about how to implement this requirement.

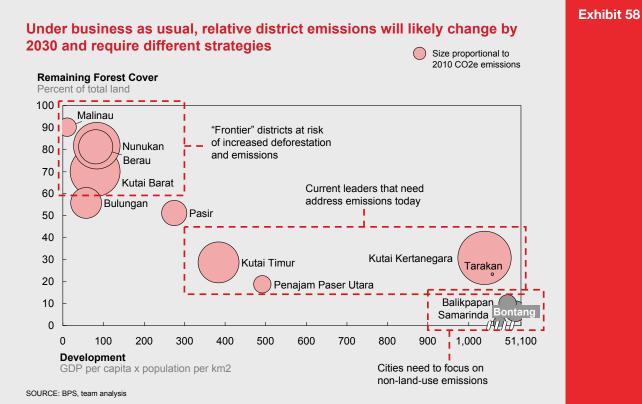

East Kalimantan needs to lobby the Ministry of Energy and Mineral Resources to address four challenges of CBM development: (1) In 2011, the central government plans to introduce new PSC regulations that will provide more flexible procedures for CBM operators. East Kalimantan should play a proactive role in collecting feedback from major CBM companies and escalating this back to the central government; (2) East Kalimantan should request that the central government permit CBM operators to import non-local equipment and supplies without having to apply for ministerial approval until local contractors and suppliers emerge; (3) East Kalimantan should take a proactive role to facilitate the negotiation processes of land access between multiple parties; and (4) East Kalimantan should work with relevant parties, such as the Ministry of Environment and Ministry of Mining, to clarify the issue of water management once for all.

## 4. District strategies

Strategies for individual districts take account of their situations with respect to the district's size and population, current land use, levels of emissions and potential for abatement, and GDP and employment for the five primary sectors. For instance, populous and urban Balikpapan has little potential for abatement, except for reforestation and working to promote operational improvements in the Pertamina refinery, but will benefit from the environmentally sustainable development strategies used in other districts, such as the development of downstream industries for the forestry sector. On the other hand, resource rich Kutai Barat has great opportunities for abatement by working with its palm oil industry in the areas of zero burning, utilization of degraded land, etc. and with its forestry industry in the areas of Sustainable Forest Management (SFM) and avoiding further deforestation. District emissions will change over time under business as usual as already deforested districts see fewer emissions from decreased land use changes while heavily forested districts today could be at the frontier for accelerated deforestation. The district strategies follow:

#### **BALIKPAPAN**

**Balikpapan is the commercial center of East Kalimantan.** The city's GDP exceeded IDR 13 trillion in 2006, it hosts the regional headquarters for many businesses, and its airport is the major entry point to East Kalimantan. Balikpapan hosts Indonesia's second largest refinery and acts as the regional base for many of the province's oil and gas companies. Oil and gas accounts directly for 40 percent of the city's GDP; the industry has also helped spur the growth of services, which account for another 40 percent of GDP.

Exhibit 59

0-1 2-5

1-2 📕 5+

#### With 5.9 MtCO2e annual emissions, Balikpapan accounts for just 2 percent of East

**Kalimantan's emissions.** Balikpapan resembles much more the industrialized world than the rest of East Kalimantan in its emissions profile. Manufacturing and services account for a sizeable share, mainly driven by consumption by the city's residents and businesses of power (1.4 MtCO2e) and transport (0.8 MtCO2e). Few emissions result from change in land use; only 540 ha are deforested a year. In addition, the Pertamina refinery alone is estimated to produce 3.3 MtCO2e from the energy consumed in the refining process as well as flaring and other process emissions (EXHIBIT 60).

#### Exhibit 60

# Refining accounts for about 3.3 Mt CO2e, half of Balikpapan's total emissions

SOURCE: Google maps, team analysis

#### The priority sectors will yield little abatement, approximately 0.2 MtCO2e. With little

deforestation, Balikpapan could reduce its forest loss only slightly, but it could reforest 22,600 ha as well as some potentially critical forest lands; these efforts would yield 0.2 MtCO2e. Balikpapan should also work with Pertamina to encourage investment in energy efficiency and reduced flaring, which could yield additional reductions by 0.3 MtCO2e. Beyond these efforts, Balikpapan could conduct a further assessment of transportation and power initiatives, such as moving to improved combustion engines for vehicles, enhanced public transport, and higher energy efficiency standards for buildings to match its developed world emissions profile.

#### Balikpapan would benefit from the potential GDP initiatives outlined for East Kalimantan.

A revival in the oil and gas industry as well as development of Coal Bed Methane would benefit the city as it is the hub for oil and gas services. Furthermore, given its port, airport, and large population, Balikpapan is a natural home for downstream industries. For example, the city already hosts more than 50 plywood and furniture companies and could benefit from a larger downstream forest products industry.

#### **BERAU**

Berau is the third largest district in East Kalimantan by land size and is still more than 75 percent covered by forests. The district's 160,000 people make it quite sparsely populated at only 5 people per square kilometer, and mining (40 percent of GDP) and forestry (30 percent of GDP) dominate the economy. Fourteen companies hold over 880,000 ha of production forest concessions and three companies hold 60,000 ha of HTI timber plantation concessions, which combined cover about 40 percent of Berau's total land. The district's large remaining forests but also the commitment of the Berau government have made it attractive as a REDD demonstration area for Indonesia.

#### The district generates over 21 MtCO2e of emissions a year, 10 percent of East

**Kalimantan's total.** Berau loses more than 24,000 ha of forest a year. The forestry sector accounts for over 10 MtCO2e p.a., primarily from unsustainable logging in the HPH concessions. In addition, there are existing location permits (*ljin lokasi*) for opening 100,000 ha of palm oil concessions, which will put additional pressure on Berau's forests. The district's emissions, mainly stemming from changes in land use, are equivalent to the emissions of 4.5 million cars.

While emissions will grow under business as usual, Berau can reduce its emissions by over 18 MtCO2e p.a. by 2030. The single largest initiative for Berau is implementing reduced impact logging (RIL) in its HPH concessions (4.7 MtCO2e abatement); the district can first target the three companies that each have over 100,000 ha of concessions. A further 3.7 MtCO2e and 1.8 MtCO2e of reductions are possible by using degraded lands for the expansion of HTI and palm oil concessions, respectively. The district has over 125,000 of very critical and critical lands that can be used for this initiative. Additional abatement comes from the agriculture and coal sectors.

**Berau can benefit from improved productivity in the forestry sector.** Berau already has East Kalimantan's only pulp and paper mill, but over the past years it has often run below capacity or been closed, due to lack of pulpwood inputs. Improving productivity in the pulpwood plantations, and more efficient use of wood from RIL forestry operations could provide enough supply to ensure the pulp and paper mill can operate at full capacity. With its water access, existing HTI concessions, and port, Berau could even potentially be the site for a new forest products industry cluster around the already existing mill, making use of timber and wood residues from the rest of the province.

#### BONTANG

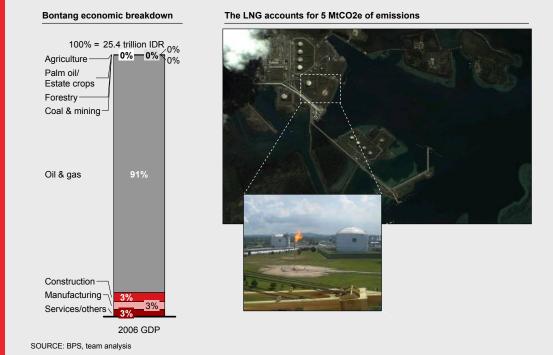

Bontang is the LNG and gas center of East Kalimantan, resulting in the second highest district GDP at over IDR 25 trillion in 2006. The Bontang LNG plant, the largest in Indonesia, dominates the city's GDP at over 90 percent of the total (EXHIBIT 61). On a per capita measure, Bontang's GDP is over IDR 200 million per person, about eight times as great as Balikpapan's. The city's development since the 1970s has followed that of two companies based on gas, PT Badak Liquid Natural Gas and PT Pupuk Kaltim, which produces ammonia and fertilizer using natural gas. However, with the decline of the province's major gas fields, the LNG plant capacity has declined to 80 percent today and is projected to decline further, particularly as Total's offshore Makaham field moves off-plateau and experiences declining production.

**Bontang has 18.5 MtCO2e of emissions which stem almost exclusively from its oil and gas industry.** With just 125,000 people and only 3,000 ha of forest, Bontang has few emissions from land-use changes, power, or transport. The LNG plant, though, is estimated to generate 15 MtCO2e as it consumes substantial energy to cool and pressurize the natural gas for transport. Emissions also result from flaring in the LNG process and from transporting the LNG to market.

**Bontang has few abatement options in the priority sectors.** The city can encourage process efficiencies and reduce emission from the LNG plant by 0.8 MtCO2e. With annual deforestation at just 150 ha, there is little avoided deforestation abatement potential.

#### Exhibit 61

#### Bontang's economy and emissions are dominated by LNG

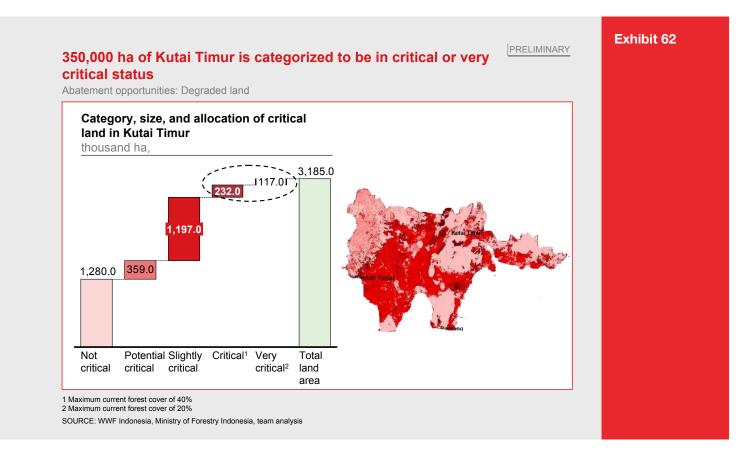

#### **BULUNGAN**

Bulungan is a large district, with over 1.8 million ha of land, but has a small population and GDP of just over IDR 1 trillion in 2006. Of all of the districts, Bulungan has the largest share of local GDP contributed by the agriculture sector, at 18 percent. The district has one of the more diverse economies with oil and gas, forestry, manufacturing, and services all contributing significantly to GDP. Currently, Bulungan has just over 20,000 ha of oil palm plantations, which contribute up to 2 percent of GDP, but the sector could see rapid expansion as oil palm location permits have been issued covering over 316,000 ha.

**Forestry, palm oil, and agriculture make up most of Bulungan's 18.1 MtCO2e of emissions, 8 percent of the province's total.** More than 7 MtCO2e of emissions stem from degradation and deforestation caused by over-logging in Bulungan's five HPH concessions of over 560,000 ha. Bulungan contains more than 1 million ha of forest (more than 50 percent of its total area), which are being lost by about 15,000 ha p.a., driven by the expansion of palm oil and agriculture and results in 2.4 MtCO2e. The district's 80,000 ha of peatland are also an important source of emissions as they are being opened for palm oil, logging, and agriculture. Annual fires in Bulungan from all palm oil, agriculture, and forestry combined account for over 5 MtCO2e.

**Bulungan has the potential to reduce annual emissions by 8 MtCO2e by 2030.** Implementing RIL in the five HPH concessions would yield 2.5 MtCO2e, and instituting and enforcing a zero burning policy can yield another 2.7 MtCO2e. Together these two initiatives would abate more CO2e than the average coal power plant emits. As palm oil plantations expand in Bulungan, it will be important to ensure that the associated deforestation is minimized. Bulungan has 77,000 ha of very critical and critical lands; if suitable plots were used for palm oil that would otherwise be developed on forest lands, then 1.1 MtCO2e of emissions would be avoided (EXHIBIT 62). The remaining abatement potential is fragmented across many initiatives in palm oil, forestry, agriculture, and coal mining.

#### With a diverse economy, Bulungan can benefit from some GDP productivity levers.

Bulungan has only one HTI forestry concession of 5,000 ha, but it is inactive; the district should focus on finding an active operator and one willing to invest to reach best-practice HTI yields in Indonesia. East Kalimantan's yields on food and estate crops are 20 percent of Indonesia's average; with agriculture still almost a fifth of Bulungan's GDP, it can boost its economy by raising farm productivity. This will require an increase in the number of extension workers, nucleus farmers, and support from private agricultural companies. As palm oil expands, Bulungan will need to ensure that concession holders fully implement the required plasma schemes. The plasma scheme is an important economic opportunity for rural households and smallholders, as participants tend to have much greater palm oil yields than independent smallholders.

#### **KUTAI BARAT**

**Kutai Barat's 3.1 million ha provide the forests and minerals that drive its economy.** Coal and mineral mining contribute 40 percent of GDP. The district was home to the gold miner PT Kelian Equatorial Mine, which until its closure in 2005 was a substantial contributor to district GDP. Forestry contributes another 12 percent of GDP from the 1.5 million ha of HPH concessions and 156,000 ha of HTI concessions. Palm oil is set for a rapid expansion from the current 90,000 ha with existing operating licenses to the 450,000 ha based on the currently issued location permits. The district remains sparsely populated with just 5 people per square kilometer. Its small population combined with the high GDP from its natural resources means that Kutai Barat's GDP per capita is approximately IDR 16 million, the same as in urban Samarinda.

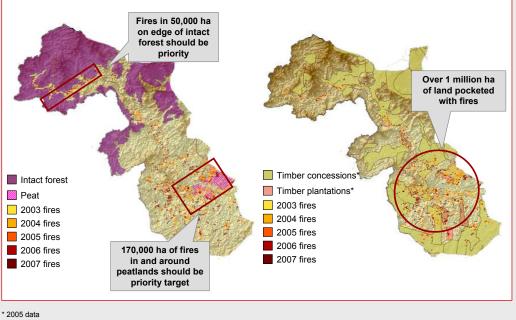

Kutai Barat accounts for 14 percent of East Kalimantan's emissions (44.5 MtCO2e) with just 5 percent of the population and 2 percent of total GDP. Forestry, mining, palm oil, and agriculture are resulted in significant land use changes in Kutai Barat. Every year, 25,000 ha are deforested, a rate of forest loss of 1.1 percent p.a. for the district. Kutai Barat also has over 100,000

ha of peatland, which is partially degraded and decomposing. Finally, on average fires cover 32,000 ha across forest and peatland per year (EXHIBIT 63). The 1.5 million ha of HPHs contribute over 8 MtCO2e from forest degradation. The fires, particularly those on peatland, contribute an additional 15 MtCO2e. Mining causes 5 MtCO2e of emissions, more than 80 percent of which stem from the associated deforestation to open the mine.

Kutai Barat has the potential to reduce business-as-usual emissions by 34 MtCO2e in 2030. A zero burningpolicy could end the 32,000 ha of fires and abate almost 11 MtCO2e. The implementation of RIL in the 1.5 million ha of HPH could abate an additional 8.7 MtCO2e. Palm oil expansion onto 160,000 ha of degraded land, rather than forest land, would yield a reduction of 2.3 MtCO2e.

#### Exhibit 63

## Kutai Barat's fires are dispersed on peatland and along the borders of timber concessions and intact forests

SOURCE: WRI Interactive Atlas of Indonesia Forests

The district has the potential to benefit from additional sources of GDP. As coal mining continues in the district, the development of CBM would yield more GDP from each concession. Kutai Barat has the potential to improve its forest sector; more than half of its 150,000 ha of HTI are currently inactive. These could be brought into production, and increasing productivity of all HTI could further boost output in this district.

#### **KUTAI KERTANEGARA**

Kutai Kertanegara is an economic powerhouse in the province with the greatest GDP of any district at IDR 28.3 trillion in 2006. The district contains much of the upstream oil and gas fields in East Kalimantan, and they account for 75 percent of GDP. There is substantial coal production as well, over 12 million tons in 2008 and the third highest in East Kalimantan. Kutai Kertanegara's large natural resources, large amounts of land, and large population distinguishes it from its neighbors. While most of the large districts in East Kalimantan have low populations, Kutai Kertanegara's 530,000 population is second only to Samarinda and greater than Balikpapan. With

substantial natural resource extraction and a population density four times greater than Kutai Barat and Kutai Timur, much of Kutai Kertanegara's lowland forests have been cleared, with the result that the district is only 30 percent forest covered today. The district also contains around 250,000 ha of peatlands, the second most of any district, but these too have been mostly deforested and drained.

With baseline emissions of 52.3 MtCO2e in 2005, Kutai Kertanegara has the largest emissions in East Kalimantan. The single largest source comes from fires, particularly on the district's exposed peatlands, which release 16.8 MtCO2e annually. Emissions from continued clearing of forests are also sizeable. Palm oil expansion into forest results in 6.0 MtCO2e. While there are already 220,000 ha of concessions with HGU approvals today, there will be continued expansion as 466,000 ha have location permits. Kutai Kertanegara has far fewer emissions from forestry than its neighbors as it has comparatively less land in HPH and HTI concessions, 480,000 and 37,000 ha respectively. In fact, most of the district's forests have been converted to uses for other economic sectors. But deforestation has not yet plateaued; mining is particular strong in Kutai Kertanegara, resulting in emissions of 5.4 MtCO2e from deforestation for mining activities, more than any other district from this source.

**By optimizing its land use, Kutai Kertanegara could reduce the carbon footprint of its current economic activities by 34.5 MtCO2e against 2030 business as usual.** The largest potential comes from instituting zero burning (9.0 MtCO2e), rehabilitating peatlands (5.4 MtCO2e), using degraded lands for oil palm expansion (3.0 MtCO2e), reforesting slightly degraded lands (2.8 MtCO2e), and stopping illegal mining (2.4 MtCO2e). Fires occur throughout most of Kutai Kertanegara's 2.7 million ha; fighting fires across such a large expanse will be costly and difficult. The priority should be to target fires in and around the district's 250,000 ha of peatland, which produce much greater emissions from fire. Rehabilitating opened peatlands and rewetting them will also help reduce the spread of fires while reducing emissions from peat decomposition.

**Degraded land offers a large opportunity for Kutai Kertanegara to reduce emissions, but the district will require significant effort to use this lever properly.** The district has 203,000 ha of critical and very critical land with low forest cover that would allow for the expansion of palm oil plantations without the high emissions of deforestation. However, only 93,000 ha of the land has plots of at least 500 ha or larger. These lands would need to be consolidated as typically a palm oil plantation needs 5,000 continguous hectares to attract investment. In addition, given the district's relatively high population density of 19 people per square kilometer, significant time and effort may be necessary to ensure that all communities in degraded lands give free and prior informed consent to use the lands for new concessions. Perhaps easier would be the reforesting of the 950,000 ha of slightly critical and potentially critical lands, as no minimum plot sizes nor consolidation would be required.

Despite already having the largest economy in East Kalimantan, Kutai Kertanegara could expand its economy faster, particularly from developing coal-bed methane and accelerating exploration and investment in oil and gas exploration. With oil and gas such a dominant part of the economy yet a relatively low source of emissions, Kutai Kertanegara can support BP MIGAS to accelerate exploration in oil and gas fields by providing regulatory incentives. In particular, it is important for the district that the Offshore Mahakam field has clear ownership and investment plans as it will soon come off plateau and need substantial new capital to slow the decline in its production. A top priority for the district would be the development of coal-bed methane as a complement to its existing oil and gas production; this requires working with the province and national BP MIGAS to ensure regulations support its rapid development. Every day that Kutai Kertanegara mines 34 thousand tons of coal without capturing CBM first, the valuable methane is released into the atmosphere; representing an increase in greenhouse gases and a permanently lost opportunity to sell that gas. Kutai Kertanegara already has three of the four blocks approved for CBM in East Kalimantan.

#### **KUTAI TIMUR**

## Kutai Timur is coal country in East Kalimantan, producing 75 million of East Kalimantan's total of 118 million tons, and providing 85 percent of the district's IDR 13.7 trillion GDP.

Kutai Timur is large by all measures: the second largest in terms of land at 3.6 million ha, the second highest GDP per capita at IDR 78 million, and the most permits issued for palm oil at 81. The district has ambitious plans for palm oil; and while it has 170,000 ha with HGU approvals (second highest in East Kalimantan), it has plans to expand more than fourfold with 838,000 ha of location permits issued, more than double any other district. Given this development, much of the district's lowland forests have already been cleared. There are still 1 million ha of forest remaining, mainly in the less accessible mountainous interior, but these are still mostly covered by HPH concessions. Kutai Timur is also home to one of the district's largest national parks, the Kutai National Park, which although ravaged by El Nino forest fires of 1997–1998, remains an important conservation area.

Kutai Timur's emissions of 31.4 MtCO2e in 2005 were the fourth highest in East

**Kalimantan.** Like the other Kutai districts, fires from all sectors are an important contributor, emitting 8.5 MtCO2e annually. Other large sources include 4.2 MtCO2e from mining, 80 percent of which is due to the associated deforestation from open pit mining. An additional 3.9 MtCO2e results from deforestation for the expansion of palm oil plantations. The combined deforestation from palm oil, mining, small holders, and all other sources results in almost 20,000 ha of forest lost each year, equivalent to 2 percent of remaining forest cover.

Kutai Timur can reduce its emissions by 31.5 against the 2030 business-as-usual scenario with a focus on utilizing degraded lands. With 350,000 ha of very critical and critical lands, it has more degraded land available than any other district. After discounting for land with plots of 500 ha or larger, there is still 160,000 ha available. These lands can be used for palm and provide 3.4 MtCO2e in abatement from avoided deforestation. Deforestation from coal mining, though, cannot be abated via land swaps with degraded lands as coal resources are fixed geographically.

With coal such a vital part of Kutai Timur's economy, the district can gain the most value from its current mining, primarily by supporting coal-bed methane and ensuring that mining sites are rehabilitated. Like Kutai Kertanegara, Kutai Timur has sizeable coal-bed methane reserves, and current coal production is releasing and wasting valuable natural gas. The district already has one CBM block: Sangatta West CBM PSC. The district can help reinforce to BP MIGAS the importance that it quickly auction further blocks as well as remove regulatory obstacles. Under its direct control, Kutai Timur should also reevaluate how it issues future licenses, as developing CBM is more difficult when many small KP licenses each have a portion of a larger coal seam, as the CBM operator would need to negotiate with many companies before starting investment. Also, with such a large mining expansion, Kutai Timur needs to put a higher priority on the rehabilitation and reclamation of post-mining lands. Over 140 thousand ha of land is estimated to be disturbed by 2030; if this is not reclaimed and rehabilitated (as is the current case with an estimated 80 percent of KP companies), then the land will be unusable for any other economic activity such as agriculture, acacia plantations, or palm oil plantations. Reclaiming, rehabilitating, and then re-using mining lands is a sizeable economic opportunity for the district.

#### MALINAU

Malinau holds the largest remaining natural forests in East Kalimantan and has retained the most forest cover at 90 percent. In fact, Malinau's 3.8 million ha of forests make up almost a third of the entire province's forest cover. Malinau can claim the smallest loss of forest, in absolute terms, at just 4,000 haper year of any district excluding the four cities. It is also the largest district at 4.2 million ha and has the smallest population and lowest population density at 66,000 people and 2 people per square kilometer. Its GDP is the lowest at IDR 485 billion. With no oil, gas, or mining, Malinau's economy depends on forestry, agriculture, and the service sector (largely from public administration). Malinau is also officially a conservation district; it is an integral part of the Heart of

Borneo conservation area as well as home to Sebuku Sembakung national park, home to the few remaining clouded leopards, sun bears, and other iconic but disappearing Borneo animals.

#### Malinau's baseline emissions were only around 8 MtCO2e in 2005, the fifth lowest in

**East Kalimantan.** More than half of all emissions come from logging. The single largest HPH concession in East Kalimantan is PT Essam Timber's 355,000 ha concession in Malinau. In total, the district has nine companies operating HPH concessions covering 765,000 ha. Unsustainable logging practices, such as poor use of skid paths, results in forest degradation and emissions of 4.7 MtCO2e. There is also approximately 2.6 MtCO2e from smallholder deforestation for agriculture. Other sources are quite small.

#### Malinau could abate 7.4 MtCO2e against 2030 business as usual, primarily through

**reduced impact logging.** Given its large areas of HPH concessions, Malinau should focus on implementing RIL. Working with the nine HPH concessionaires to implement skid paths, use winches (as opposed to bulldozers), and other RIL methods could yield the same amount of saleable timber from the concessions but with 30 to 50 percent less emissions, as less collateral biomass is destroyed in the logging process. Malinau also has almost 90,000 ha of degraded land that can be used for expansion of agriculture and palm oil. While there are no palm oil concessions yet with HGU approval, eight concessions utilize as much of the existing degraded land as possible. Given that the palm oil concessions, its environmentally sustainable development strategy needs to focus less on reducing emissions from existing activities than ensuring that future growth comes from higher-value added activities or low carbon sectors.

#### More than 40 percent of Malinau's GDP is derived from forestry, which is thus an

**important sector for growth.** Given its large HPH concessions, it is important to ensure that as much value as possible is gained from the logging activities. One way is to ensure high utilization of harvested logs, so that in addition to using the lower tree areas for plywood and veneer the concessionaires use the smaller branches for pulp and paper and wood pellet production. While Malinau's inland position makes it an unfavorable location for a pulp and paper mill, the district can focus on other downstream forestry products, such as niche wood products and non timber forest products.

**Agriculture will also remain important for Malinau.** Agriculture provides income to the rural villages in Malinau and currently makes up 6 percent of GDP. While Malinau's low population has fewer smallholders to reach, they are scattered throughout the district, which makes improving agricultural productivity more challenging. Growing more estate crops in addition to staple crops on small plots of degraded land can also boost GDP.

#### NUNUKAN

Nunukan, the large district on East Kalimantan's northern border, has abundant forests and peatland as well as a diverse economy. Like its neighbor Malinau, Nunukan retains much of its forest cover, more than 80 percent. But unlike Malinau, Nunukan has substantial peatlands, over 400,000 ha, more than any other district of the province's total. Its IDR 1.2 trillion GDP is fairly diverse: oil and gas from the district contributes 30 percent of GDP, services account for 20 percent, forestry 16 percent, coal 13 percent, agriculture 11 percent, and palm oil 3 percent.

Nunukan has substantial emissions with a baseline of 40 MtCO2e in 2005, almost onefifth of the province's total. While Nunukan does not have the highest level of deforestation nor the largest population, damage to its abundant peatlands have pushed up its emissions. Smallholder fires spread across degraded peatlands, causing 16 MtCO2e of emissions annually. Likewise, Nunukan's 278,000 ha of HPH concessions partly cover its peat forests; the logging leads to peat decomposition emitting 6.8 MtCO2e, much larger than the 1.5 MtCO2e resulting from unsustainable logging practices. Nunukan has few palm oil concessions, just 78,000 ha with HGU licenses, and there is currently little expansion, as only 97,000 ha have location permits. These palm oil concessions, though, do overlap with the district's peatland, and the required drainage of peat to grow oil palms exposes the peat's carbon to air; the decomposition releases 7.1 MtCO2e.

The key to reducing Nunukan's emissions is better management of its peatlands, which can provide 8.9 out of the 25 MtCO2e abatement potential against 2030 business as usual. Fortunately, most of Nunukan's fires are concentrated; the district could capture most of the total abatement from a zero burningpolicy for agriculture (7.2 MtCO2e) by focusing on just 50,000 ha of peatland. Maintaining water levels and reducing drainage in peatland can reduce emissions by another 3.6 MtCO2e. Likewise, rehabilitating peatlands in agriculture and forest concessions can yield 2.1 and 4.0 MtCO2e abatement respectively. There would also be gains from instituting reduced impact logging in the five current HPH concessions (1.5 MtCO2e potential) and using some of the district's 133,000 ha of degraded land for palm oil expansion (1.9 MtCO2e potential).

With a diverse economy, good access from its ports, and proximity to Malaysia, Nunukan has the potential to move into downstream products as well as increase its economic productivity. Nunukan should join the efforts to lobby BP MIGAS to improve the regulatory policies to encourage oil and gas exploration as well as coal-bed methane. While Nunukan is not part of the massive Kutai Basin that holds most of the province's oil and gas reserves, it does partially overlay the Tarakan basin. Nunukan can also benefit from raising the productivity of its agricultural and palm oil sectors, which make up 14 percent of the district's economy. And while the district currently has no HTI concessions, with 133,000 ha of degraded land, it has the potential to develop acacia plantations without deforestation.

#### **PENAJAM PASER UTARA**

**Penajam Paser Utara is a relatively small coastal district.** It is the smallest district at 330,000 ha, but has a long coastline with 65,000 ha of beaches. With 37 people per square kilometer, Penajam Paser Utara has the highest population density outside of East Kalimantan's cities. Its GDP per capita is equal to that of Samarinda. Oil and gas make up 45 percent of the economy, but most of the population is engaged in agriculture and fishing, which accounts for 9 percent of GDP. The district also has a significant manufacturing sector making up 19 percent of GDP, mostly agricultural processors and industrial manufacturers located near the border with Balikpapan. The district's lowland location means its forests are easily accessible and thus have largely been utilized. Only 19 percent of its forest cover remains, less than any district, yet forest loss continues with an annual loss of 5,000 ha (equal to 8 percent of remaining forest cover).

With largely degraded lands and a small size, Penajam Paser Utara's baseline emissions were only 6.3 MtCO2e in 2005, the lowest in East Kalimantan. The largest source is from deforestation, from expansion of agriculture and palm oil, at 2.7 MtCO2e. While there are currently only 27,000 ha of HGU-licensed concessions, palm oil could expand more than four-fold with 130,000 of location permits granted to 14 companies. Additional emissions of 2.1 MtCO2e stem from logging of the district's remaining forests.

**Abatement potential is estimated to be 6.3 MtCO2e against business as usual identified.** The largest abatement would be from using the district's 20,000 ha of degraded land for expansion of agriculture and palm oil, yielding 2.5 MtCO2e in abatement. There is abatement potential from zero burning and reforestation, but this is small at 0.3 and 0.4 MtCO2e respectively. Reduced impact logging of the remaining forest is important and could yield 2.6 MtCO2e abatement in 2030.

**Penajam Paser Utara has the potential to boost its GDP among its diverse sectors.** With oil and gas contributing so much to GDP, the district can support the province's efforts to work with BP MIGAS to accelerate exploration and ensure maximum investments in current fields. With a substantial part of its population involved in agriculture, aquaculture, and fishing, raising productivity in these sectors is important and will require support from extension workers and nucleus farmers. The compact district's coastal location and proximity to Balikpapan makes it a prime candidate for high-value niche crops such as oranges as well as a base for downstream

agricultural processing. As Penajam Paser Utara develops its palm oil sector, it is important to ensure plasma schemes are implemented, whereby plantation owners support surrounding smallholders of oil palm. Finally, the district has one HTI concession of 16,000 ha, the district can encourage the concession holder to invest to ensure best practice yields.

#### PASIR

Pasir, on East Kalimantan's southern border, has a sizeable IDR 1.6 trillion economy with substantial coal deposits. Two-thirds of GDP comes from coal mining and agriculture and palm oil contribute significantly at 9 percent and 6 percent respectively. Its GDP per capita is roughly equal to that of Samarinda. Despite its development of natural resources, Paser still retains 50 percent forest cover, mainly in the mountainous interior.

**Pasir's 2005 emissions were approximately 12.3 MtCO2e in 2010, 6 percent of the province's total.** Land devoted to palm oil is expanding, from 95,000 ha with HGU to a potential 267,000 ha with IL, resulting in emissions of 2.1 MtCO2e from deforestation and an additional 1.6 MtCO2e from smallholder fires. Paser has 197,000 ha of HPH concessions; unsustainable logging practices in those areas produce annual emissions of 2.4 MtCO2e.

While emissions will grow under business as usual, there is potential to reduce emissions against business as usual by over 9.8 by 2030. Sustainable forestry in the HPH concessions could yield 1.2 MtCO2e in abatement; with just four companies, Pasir can easily monitor all of them as they implement reduced impact logging. Currently, there is only one HTI and that is for 9,000 ha, but it is inactive; however, moving future HTI expansions to degraded land could yield 2.4 MtCO2e in reductions. There is over 375,000 ha of suitable for reforestation (as opposed to land swaps for palm oil or acacia plantations); this would provide 1.1 MtCO2e abatement.

**GDP improvement can come from improved productivity as well as increased use of degraded lands.** Pasir has relatively large amounts of very critical and critical land, 173,000 ha, that can be used to expand agriculture and acquaculture. In particular, Pasir can encourage the growing of high-value estate crops in the smaller plots by smallholders. With agriculture and palm oil making up 15 percent of the economy, raising the yields could improve GDP significantly as well as rural incomes. Finally, Pasir can find an active operator for its one existing HTI concession.

#### **SAMARINDA**

Samarinda, on the banks of the Mahakam river, is East Kalimantan's capital and

**largest city.** With a population of 620,000, it is larger than Balikpapan. Whereas Balikpapan is a commercial center, Samarinda is East Kalimantan's adminstirative center. Two-thirds of its IDR 9.9 trillion economy is from services, mainly public administration; Samarinda is home to the provincial ministries, parliament, as well as other agencies. The city is also home to the large Mulawarman University with over 33,000 students. While the city has no palm oil or forest plantations, it does contain coal deposits, which generate 4 percent of GDP.

With just 3.3 MtCO2e in emissions, Samarinda is less than 2 percent of East Kalimantan's total emissions. As the city comprises only 72,000 ha and is already primarily deforested, there are few emissions from changes in land use. However, Samarinda does have small amounts of peat, around 20,000 ha, which are degraded and decomposing, releasing an estimated 1.7 MtCO2e. However, most of the city's emissions are due to the power and transportation needs of its manufacturing and service sectors, which combined produce 2 MtCO2e.

**Samarinda's abatement options will yield small reductions but can be symbolic.** With low current emissions, there is not much room for reduction. As the province's capital, though, Samarinda's abatement initiatives can have symbolic value. Events such as the Kaltim Green Bike Event can demonstrate commitment to reducing emissions from transportation. Rehabilitating

the city's peatlands would also be an important visible act. The city's 38,000 ha of potentially and slightly critical lands can also be reforested under the Kaltim Green One Man Five Trees program.

#### TARAKAN

**Tarakan is East Kalimantan's only island city, with an economy built on trade and tourism.** Its location near Malaysia has made it a natural crossing point between the two countries with daily ferries. Its IDR 2.1 trillion economy is dominated by the service sector (70 percent of GDP), which is focused on trade, hotels, and tourism. Manufacturing (11 percent of GDP) and agriculture (10 percent) are the other main sectors. The smallest city, Tarakan has retained more forest cover than the other cities with 20 percent remaining of its 25,000 ha. This includes mangrove forests, which are particularly important as they protect the island's coasts from extreme weather conditions.

**Tarakan also has the smallest CO2e emissions with a baseline of 0.3 MtCO2e in 2005.** Tarakan is losing around 800 ha of forest a year, out of only 5,800 ha remaining, deforestation results in 70 percent of its emissions. Deforestation results in 70 percent of its emissions. The remainder is due to power consumption and transportation for its service and manufacturing sectors.

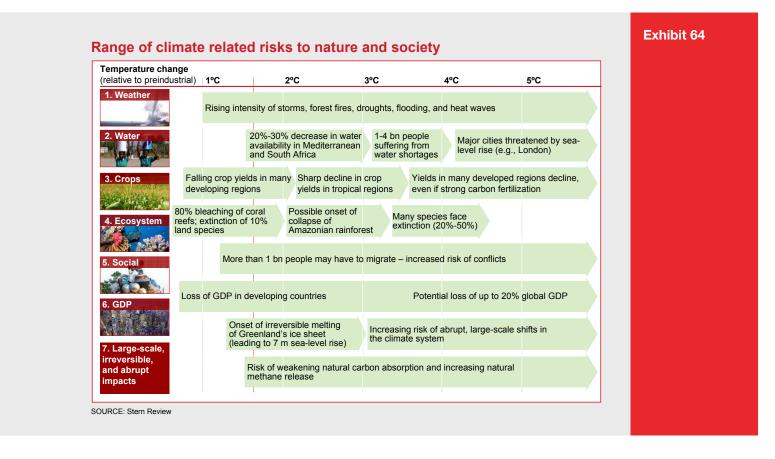

**The city will have to look for small-scale improvements to reduce emissions.** Stopping current deforestation could yield 0.1 MtCO2e of abatement. In addition, Tarakan has 7,000 ha of slightly and potentially critical lands that can be reforested under the One Man Five Trees program. Beyond these efforts, Tarakan could conduct a further assessment of transportation and power initiatives, such as moving to improved combustion engines for vehicles, enhanced public transport, and higher energy efficiency standards for buildings to match its emissions profile, which is more like that of a developed city than the large forested districts.

## 5. Adaptation

**Climate change poses significant potential risks to economies and people.** Like many other countries, Indonesia is vulnerable to climate events such as floods, tropical storms, and other severe weather disasters. Climate change could significantly increase those risks as the increase in greenhouse gas emissions will result in changes in global air temperatures, frequency and amount of rainfall, and sea levels and temperatures. Climate change plays havoc on local economies through event hazards and gradual shift hazards. Event hazards are extreme weather events like storms, hurricanes, droughts, coastal flooding, inland flooding, and fires. Gradual shift hazards are gradual rises in sea levels and salinisation and climate zone shifts that impact agricultural yields or spread of vector-borne diseases such as malaria.

An adaptation strategy recognizes that some level of climate change is inevitable and seeks to prepare the economy and population to be more resilient to the negative effects of such climate changes. Even under the optimistic IPCC scenario, under which the world takes substantial action to cut current greenhouse gas emissions, atmospheric greenhouse gases are expected to reach 450 parts per million, resulting in a global warming of 2°C. In addition, IPCC's Fourth Assessment Report shows that global warming to 2030 will be little influenced by greenhouse gas emissions in the next 20 years due to lags in the climate system. Thus, countries need to adopt adaptation measures to protect their people and economies from the negative effects of increasing climatic risks that will occur in the medium term.

The IPCC predicts several scenarios for global climate change reflecting the uncertainty of the world's future greenhouse gas emissions. The B1 scenario assumes that the world moves toward an environmentally sustainable model and average temperatures increase by just 1.5°C by 2100. A scenario of rapid economic growth and balanced energy sources (A1B scenario) would see a 2.4°C increase by 2100. Finally, a scenario in which the world is economically focused

with slow and minimal efforts to adopt and share new technology and abatement measures (A2 scenario) could see a temperature rise of 3.2°C by 2100.

East Kalimantan will likely have less temperature change but greater precipitation change than the global averages, due to its geographic and climatic characteristics

(EXHIBIT 65). Changes in temperature are amplified toward the poles; since East Kalimantan is located along the equator and is in close proximity to the ocean, it will experience lower than average temperature increases from climate change. Thus, for every 1°C increase in global temperature, it is predicted that East Kalimantan will experience a 0.9°C increase. This implies that in 2030, East Kalimantan could see a 0.3 to 0.6 °C temperature increase compared to 2010. By 2030 by the best estimate, East Kalimantan is predicted to experience a 0.7 mm increase in its average monthly rainfall, but the range of prediction is wide, from a decrease of 4.6 mm to an increase of 4.0 mm. There should be no significant deviation for East Kalimantan from the global average rise in sea levels; it is predicted that sea levels along the province's coastline could rise by up to 20 cm by 2030 and 1.0 m by 2100.

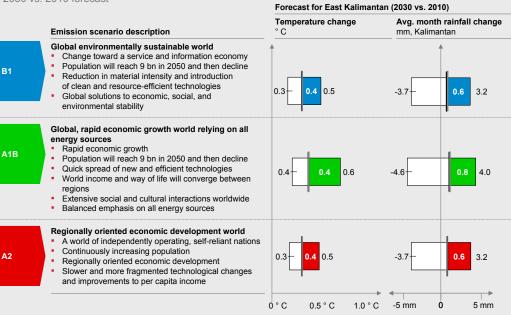

A preliminary diagnostic for East Kalimantan indicates that it will be relatively wellinsulated from most climate change threats, such as storms, landslides, and droughts. East Kalimantan is located away from major tropical cyclone pathways due to its close proximity to the equator (storms typically originate at latitudes higher than 10°), and thus it is not likely to face greater threats from storms and cyclones. Landslides are much more common in Java and Sumatra than in East Kalimantan. According to the Agency for Disaster Management there were only 10 to 12 major landslides in East Kalimantan in 2008 and 2009, and they affected 30 households. Landslides could increase with greater deforestation, but East Kalimantan's low population density reduces the pressure for migrants to build structures in vulnerable areas, so there is less likely to be more substantial loss of life or housing. Historically, droughts have not been an issue for East Kalimantan, given its regular monsoon rains; climate change forecasts actually

predict increased precipitation for the region. There is also a weaker link between climate change and droughts although there is a link to the El Nino Southern Oscillation (which in turn is linked to the low rainfall and dramatic spread of man-made fires in 1997 and 1998 in East Kalimantan).

Agricultural yields could be significantly affected. Whereas many plant species are adapted to seasonal temperature variations, tropical species typically have a much lower tolerance for changes in temperature. The World Bank predicts that by 2050 Indonesia could see a 10 percent decrease in major crop yields due to temperature and rainfall changes. Finally, vector-borne diseases can increase, as dengue- and malaria-carrying mosquitoes expand their habitats with rising temperatures. East Kalimantan currently has a low incidence of malaria; its future moderate temperature increase compared to global averages and mountainous interior (higher altitudes with lower temperatures) could serve to moderate any expansion of the habitat of vector-borne diseases.

East Kalimantan has extensive coral reefs, 86 percent of which are considered at risk.<sup>22</sup> Indonesia's longest continuous barrier reef system, the Sunda Barrier Reef, some 630 kilometers long, lies on the edge of the Sunda Shelf. It is largely unexplored despite its size and potential economic, social, and biological importance. East Kalimantan's coral reefs are impacted by climate change in three ways. Coral bleaching occurs during abnormally high temperatures in the ocean and kills coral if they last more than two weeks. Coral drowning occurs when coral cannot grow fast enough to keep up with rising sea levels. Oceanic acidification occurs as more CO2 is dissolved in the ocean and disturbs coral growth.

However, the threats of coastal flooding and inland flooding could pose a moderate risk to the province overall and potentially substantial localized risk to specific districts. East Kalimantan has 1,185 km of coastline, 368 small islands, and several coastal cities, such as Tarakan, Bontang, and Balikpapan. While East Kalimantan is relatively protected from event-driven (or storm-driven) coastal flooding, it is susceptible to coastal flooding from gradual rises in sea

level. Inland flooding has been a significant threat to areas such as the Mahakam delta and the capital city of Samarinda, which have substantial populations.

#### **COASTAL FLOODING**

**East Kalimantan has 194,000 ha of land that is vulnerable to coastal flooding.** While sea levels are estimated to rise by 20 cm by 2030, the threat is heightened as factors such as storms and the El Nino Southern Oscillation can amplify waves and the amount of land at risk of inundation. Given these factors, land that is less than 1 meter above sea level (ASL) is typically considered vulnerable. East Kalimantan has 194,000 ha that 1 meter or less ASL. Although this represents just 1 percent of the province's land, four districts have disproportionally greater areas at risk: Tana Tidung (10.2 percent of its area is vulnerable), Samarinda (4.2 percent, although this land is more vulnerable to inland rather than coastal flooding), Bontang (3.8 percent), and Tarakan (3.6 percent). These estimates likely underestimate the threat to East Kalimantan's coasts, though, as elevations are measured by satellite<sup>23</sup> which can not penetrate East Kalimantan's dense forests. An estimate of land that is 20 meter ASL or less, while certainly an overestimate, would compensate for low elevations covered in forest and gives an upper bound of over 2 million of vulnerable lands.

#### Exhibit 68

#### 1% of East Kalimantan's land is vulnerable to coastal flooding

	Area less than 1 m ASL Ha	As percent of total area

SOURCE: Radar Topography Mission (SRTM), team analysis

#### Coastal flooding will have a disproportionally large economic impact on East

**Kalimantan.** Although the area that is vulnerable to coastal flooding is relatively small, it contains some of the province's largest assets. East Kalimantan's single international airport, Seppingan airport in Balikpapan, is on the coast and less than 1 meter ASL; Tarakan's airport is similarly vulnerable. The multi-billion dollar LNG plant in Bontang, the single greatest capital investment in the province, is at risk. Similarly, the Pertamina refinery on the coast in Balikpapan is on vulnerable land. These two assets generated more than 27 percent of all of East Kalimantan's GDP in 2008.

In addition to the refinery and airport, much of Balikpapan's commercial and residential assets will also be vulnerable to coastal flooding.

Source. Radar ropography mission (Srenin), team analysis

#### A combination of hard and soft mitigations will be needed to adapt to coastal flooding.

Making East Kalimantan's major economic assets, such as airports and the refinery, more flood resilient justifies investment in infrastructure measures such as sea walls and dikes. Low level farmland could be more economically protected by restoring and protecting the provinces' natural mangrove forests, which reduce wave intensity and inundation. Better disaster planning is critical for Balikpapan, a city with significant vulnerable urban areas; being able to quickly deploy sandbags, providing shelter for those whose homes are flooded, and facilitating access to insurance and credit will all help the city adapt to any increase in coastal flooding.

#### **INLAND FLOODING**

**Inland flooding has been a challenge for East Kalimantan, displacing 80,000 people since 2007.** The province has experienced at least 50 inland flooding events in the past four years. Most of these floods have been small, lasting just one day and reaching less then 0.5 meters in height. There are, however, occasional floods that are more severe. In June 2007, a month long flood in Kutai Barat and Kutai Kertanegara inundated over 34,000 square kilometers and displaced 60,000 people. In September that year, a flood covered Balikpapan in over 1 meter of water and caused the deaths of 4 people. In April 2009, flooding closed much of Samarinda and resulted in 20,000 people fleeing their homes. As climate change is forecasted to increase monthly precipitation in East Kalimantan (best estimate 0.7 mm increase, range of -4.6 to +4.0 mm), there is a risk of increased inland flooding; however, the relationship between inland flooding and rainfall depends on frequency and intensity of rainfall and not just the average amount, thus more study of rain patterns as well as specific hydrological characteristics of the province's rivers is needed to fully understand the climate change impact on inland flooding in East Kalimantan.

#### Exhibit 70

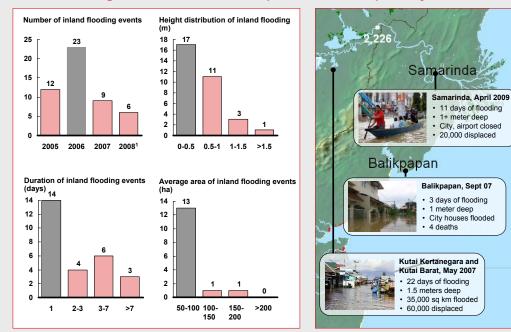

#### Potential coastal flooding infrastructure or asset based countermeasures

Measure	Description
Build dikes	Permanently and absolutely hold back sea level in high-risk areas using 10 km-long, 4 m-high coastal dike system
Develop mangrove buffer	Restore and expand natural coastal mangrove buffer to 100m thickness in order to dissipate wave energy and reduce flooding risk
Expand reef and sandbar system	Restore reefs and/or build offshore sandbars to dissipate wave energy offshore and reduce flooding risk from storm surges
Build sea walls in strategic locations	Armor coastline with rock revetments in populated areas, to dissipate wave energy and prevent erosion
Create offshore breakwaters	Build concrete and rock structures offshore and parallel to coastline to reduce wave energy reaching shoreline
Nourish beaches	Import or relocate sand from elsewhere in the islands or offshore to keep beaches at constant width despite erosion
Raise elevation of coastline	Build coastline upwards with material sourced from elsewhere on the islands (e.g. as in the Maldives)
Relocate existing infrastructure/housing in hazard zones	Move existing housing and commercial buildings in area of risk (below 4 m elevation) to higher elevation
Elevate all existing near- shore structures	Modify existing near-shore structures below 4 m elevation to be elevated on 2 m high stilts, as in parts of SE Asia
Elevate all new near-shore structures	Continue to build in hazard zone, but require that all new structures be elevated on 2 m stilts, as in parts of SE Asia

#### The greatest economic risks from inland flooding is concentrated in Samarinda and

**Balikpapan.** The two cities contain half of the province's population as well as much of the major businesses and factories; thus, they have more at stake simply by having more assets. Urban areas are also more vulnerable due to their higher population concentrations and fixed assets; these are exacerbated by poor drainage systems. Rural communities, especially those located on flood-prone rivers, are more resilient to changing flood levels by building floating homes or houses on stilts that can be adjusted.

#### Exhibit 72 Adaptive capacity of rural coastal plains is higher than urban areas Rural communities that historically lived close to ... while urban areas with higher population the river developed techniques to adapt .. concentrations and fixed assets struggle River communities have for centuries managed Flooding in urban areas has historically been a and adapted to changing flood levels by key risk because of severe rains and a large building floating homes or houses on adjustable low-gradient river system stilts Lack of drainage and poorly maintained and Farming activities and transportation might be cleaned sewage systems result in slow affected in the long term requiring populations drainage in urban areas to relocate Houses built on stilts along the Mahakam Flooding after rains in Samarinda, March 2010 SOURCE: Mr Nathan, Munich Re, Kaltim Post, literature search

#### Adaptive measures to inland flooding require both upstream and downstream initiatives.

Watersheds in the upstream areas of rivers play an important role in regulating rainfall in rivers. Preserving these watersheds from logging or conversion to agricultural land or plantations will mitigate any increase in inland flooding. A simple yet effective downstream measure is hiring staff to clean garbage out of the storm and sewer system to allow for better drainage. Like in coastal flooding, better disaster management including warnings and emergency shelter, is an important tool for both cities' to adapt to inland flooding.

#### **PILOT PROJECTS**

#### Adaptation for coastal flooding in Balikpapan is a potential pilot project for East

Kalimantan. To implement the identified adaptation measures above, more in-depth analysis is needed on the cost-benefits of each. Balikpapan is a large city with many highly valuable assets and thus a good target for more analysis; coastal flooding is also a clear threat. The first step will be to model the economic losses by creating granular spatial maps of Balikpapan's residential and industrial assets and overlapping these with various coastal flooding scenarios. The long list of coastal flooding countermeasures would need to have their costs estimated and compared to their ability to reduce the negative impact of the flooding. The prioritized initiatives will be included

in development plans. In addition, there is potential to partner with insurance companies to help conduct these analyses as well as provide financial risk-sharing mechanisms.

## 6. Implementation and enablers

Achieving successful environmentally sustainable economic growth will require new kinds of behavior and capabilities within government and the broader society of East Kalimantan. From an institutional standpoint, some of the challenges are organizational, as supporting environmentally sustainable growth requires coordination across the various government departments that will be critical to its success (e.g., planning (Bappeda), forestry, environment, agriculture, tourism, education, public works). Another challenge will be to build the capabilities within government to carry out this ambitious and urgent program, and to manage the stresses it creates. As with governments in other developing regions, the provincial administration of East Kalimantan is doubly challenged by critical priorities and constrained resources.

Strong leadership will be required to overcome the organizational challenge, build capabilities and change mindsets towards development across the province. While individual institutional enablers are explored in each sector strategy, five cross-cutting enablers have been identified:

- Governance and climate change institutions
- Spatial planning and policy
- Monitoring, reporting, and verification (MRV) and carbon accounting
- Community engagement
- Financing

#### **GOVERNANCE AND CLIMATE CHANGE INSTITUTIONS**

Governance over natural resources is one of the greatest challenges facing any government. Resource governance can rarely be improved in isolation, but must be part of a larger program of governance reform, such as Indonesia has been implementing over the past decade. Beginning with the Regional Autonomy Law of 1999, decentralization has brought substantial changes. Efforts to improve law enforcement and combat corruption, generally and within natural resource sectors, have yielded important results, and perhaps most importantly, a sense of momentum and optimism.

But governance of natural resources in Indonesia is still complex, and often contested. While much authority over the areas outside the forest estate (Kawasan Hutan) has been given to local district governments, roles have been undermined by conflicting regulations from central government ministries and frequently-altered procedures. The provincial government certainly recognizes that much progress is needed to better incorporate stakeholder input, particularly from communities. Capacity to collect such feedback is limited, and mindset changes and institutional improvements may be needed to insure that such feedback is effectively incorporated in planning and decision making processes at all levels. Roles of companies and their relationships with rural communities remain unclear. Large areas of the forest estate lack a strong government presence, and are very hard to police and monitor.

**East Kalimantan's governance of climate change has developed organically as the threat has become clearer and more prominent.** This is quite a common pattern, as any governments respond to new challenges by first empowering existing institutions to take on larger tasks before establishing new institutions. As the threat from climate change has grown in priority, East Kalimantan has established a number of institutions to provide capacity for specific threats. East Kalimantan has likewise created several new institutions to coordinate its response to climate

change issues. In December 2009 after participating in COP 15,<sup>24</sup> the Governor of East Kalimantan created the Kaltim Green taskforce. Then in May 2010 he issued a decree establishing a new Kaltim REDD taskforce to coordinate REDD and peatland rehabilitation efforts in the province. These institutions provide an excellent basis to coordinate the broader environmentally sustainable growth activities in the province. Both institutions report directly to the Governor and have a mandate to coordinate efforts at the provincial and district levels.

Again, it is a relatively common pattern for a number of groups to be established to look after various aspects of an urgent and highly complex cross-cutting issue. Many existing institutions have overlapping responsibilities, and no one single agency has a complete overview. At a certain point, it may become necessary to establish an umbrella organization that both can have oversight and steers the activities of different taskforces. Many governments facing the urgent and complex challenges have resorted to a coordination structure that focuses on ensuring delivery of critical priorities across a complex policy landscape.

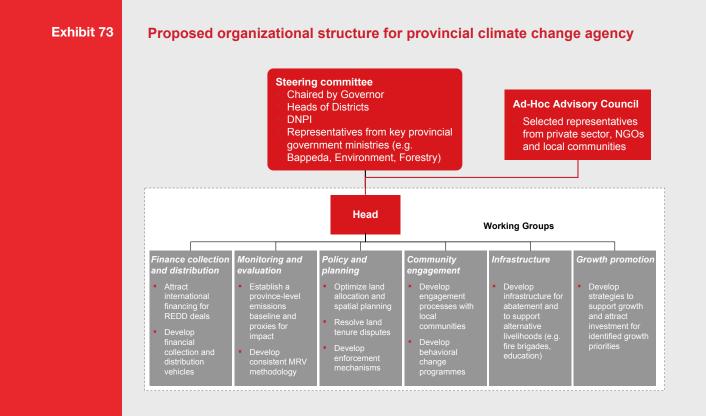

There is one strong example in the Indonesian experience. In Aceh, following the devastating tsunami in late 2004, the Indonesian Government established the Agency for the Rehabilitation and Reconstruction of Aceh and Nias (BRR) to coordinate and oversee the multi-year reconstruction process. As with moving to an sustainable economic development, recovery and reconstruction in Aceh required a new order of community outreach, a high order of coordination across many levels of government, responsible disbursement of external funding, and mobilization of technical and financial resources from across (and outside) the country. Box 9 discusses five lessons from BRR.

A review of the BRR and other domestic and international delivery units reveals some lessons that East Kalimantan will keep in view while developing its own institutional mechanisms for ensuring the successful implementation of a environmentally sustainable growth strategy (Box 9).

International and Domestic Lessons on Organizing a Delivery Unit for Complex and Urgent Development Challenges	Box 9
1. Delivery unit must have a direct relationship with and a clear mandate from the highest levels of government (e.g., Aceh's BRR, Morocco Economic Development Board, Guyana Presidential Delivery Unit)	
2. Delivery unit needs to include representatives from different levels of government and non- governmental organizations (e.g., Brazil's Amazon Fund, Indonesia's Waclimad)	
3. Relationships and decision-making rights must be clearly defined between the new delivery unit, existing ministries, and other stakeholders (e.g., Bahrain's Economic Development Board)	
4. Employee compensation and value proposition must be competitive with the commercial sector to attract top talent (e.g., Aceh's BRR, Guyana Presidential Delivery Unit)	
5. Delivery unit works best if it can develop rigorous performance management around a few priority outcomes (e.g., Bahrain Economic Development Board)	

The two case studies of ongoing projects in East Kalimantan that follow illustrate some of the organizational innovations useful for the new Climate Change Agency. The Berau Forest Carbon Program is a comprehensively designed potential REDD demonstration program at the district level and thus has lessons for how to organize a province-wide program. The Heart of Borneo is a cross-district (as well as cross-national) program that is focusing on conservation and sustainable development and has lessons on how to work across levels of government.

<sup>24</sup> UNFCCC Conference of Parties in Copenhagen, December 2009

#### Governance Case Study 1: Berau Forest Carbon Program

The BFCP will be managed under the authority of a multi-stakeholder supervisory council supported by a secretariat. A joint working group of sectoral agencies, other stakeholders, and technical experts will support program design and implementation.

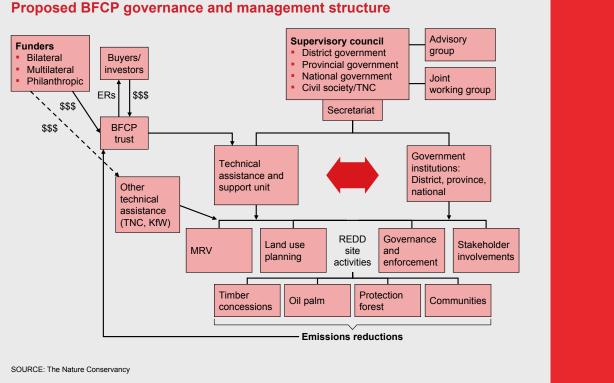

Select examples of the purpose and roles of the various groups depicted in the BFCP Structure Diagram (EXHIBIT 74) are as follows:

**Supervisory Council (SC)** is the principal governance body that holds ultimate authority and responsibility for technical and financial direction of BFCP on behalf of the Government of Indonesia. The Council is composed of senior officials appointed by the Berau District Head, the East Kalimantan Governor, the Ministry of Forestry, and other national government agencies, TNC, and members representing communities and other stakeholder groups. Its key responsibilities are: strategic direction of the BFCP, financial management, recruiting, carbon trading, stakeholder relations, support alignment of government resources, and sustainability of the BFCP.

**BFCP Trust Fund** is to receive funds from donors and potentially from carbon offsetters and distribute them to program implementers and beneficiaries. Public and private funders would contribute funds to the BFCP Trust Fund according to an agreed schedule and will receive annual progress and financial reports as well as periodic updates. Donors will be requested to provide funds with the least restriction possible to enable flexible implementation of BFCP programs.

**Communities** will have representatives sit on the Community Advisory Board to give input to the SC in managing the BFCP on cross-cutting issues related to community involvement in low-carbon development and more broadly on governance. Community leaders will be involved with Joint Working Group meetings and processes. The BFCP will directly engage target communities

Exhibit 74

to support governance and natural resource management. Communities adjacent to any BFCP site will be directly involved in the development and implementation of BFCP activities.

#### **Governance Case Study: Heart of Borneo**

In April 2005, delegations from Indonesia, Malaysia, and Brunei Darussalam met to launch the Heart of Borneo Initiative. The three countries agreed to manage a cross-border area based on conservation and sustainable development principles. The Heart of Borneo covers around 22 million hectares, and the largest portion (28 percent) in any province or state lies in East Kalimantan with 6.1 million hectares of the total Heart of Borneo land area.

Given that the Heart of Borneo crosses not only districts and provinces but three countries, the project has developed a multi-layered governance structure that is a useful example (Table 3).

#### **SPATIAL PLANNING AND POLICY**

Given that the majority of East Kalimantan's emissions are due to the conversion of forest and peatlands, the most critical regulatory issues are resolving land tenure and title disputes and optimizing land-use allocation through better spatial planning. Collaboration among national and district level governments will be critical due to the cross-jurisdictional nature of land tenure and spatial planning issues. In addition, any collaboration needs to be supported by detailed technical analyses, which can accurately assess current land allocation and the potential economic benefits of using land types for different activities. Box 10 discusses the current levels of spatial planning.

A single land titling system to register deeds and map land holdings is a necessary tool, and such a system does not currently exist. Technology offers ways to more cost- and time-efficiently build such a database. Indonesian planners recently built such a system in Aceh after the tsunami, overcoming

Table 3

#### HEART OF BORNEO GOVERNANCE STRUCTURE

Level	Structure	Activity	Person in charge
Trilateral	There is no agreed institutional structure yet. Until now, the highest forum is a Trilateral Meeting	<ul> <li>Annual trilateral meeting (commitment, exchange ideas and information)</li> <li>International outreach (fundraising, awareness, conflict resolution)</li> <li>Strategic Plan of Action (SPA) as joint activity base Related departments in each country</li> </ul>	<ul> <li>Related departments in each country</li> </ul>

#### **Box 10**

#### Multiple Levels of Spatial Planning

Multiple levels of planning have important implications for environmentally sustainable development and improved planning at all levels needs to integrate carbon and CO<sub>2</sub> emissions as an explicit consideration.

**Propeda (Program Pembangunan Daerah)** are long-term strategic plans that lay out infrastructure plans, major economic development investments, and long-term goals.

**RTRWP** (*Rencana Tata Ruang Wilayah Provinsi*) is a national system of spatial planning that maps broad areas into production forest, protection forest, and non-forest areas that determine which major land uses are allowed.

**Permitting and licensing is the purview of** district, provincial, and national government agencies, which make important decisions about whether and where to site concessions within spatial plan zones with tremendous implications for emissions.

Land use planning within license areas is done by land owners, managers and the stakeholders who make important decisions about land use that affect carbon emissions, social, and biodiversity outcomes.

**Box 11** 

**Box 12** 

the lack of a strong system, the particular challenges of how long-term armed conflict had shaped claims about customary rights, and the loss of physical records due to the disaster. This exercise shows that land titling and spatial planning mix complex, historical, social, economic, and political issues, and that close community support is essential for these initiatives. The backbone of such a system is a community engagement approach that undertakes community-based land mapping and land adjudication, builds institutional capacity at the local level, ensures the process is done in a fair and transparent manner, and clearly communicates the benefits to the local people.

Environmental Impact Assessments (AMDAL) are very important tools for managing spatial planning and the process of licensing and permitting. But the role of assessments also needs to be strengthened, so that they provide a rigorous consideration of environmental concerns before licenses are issued. Assessments should be broadened to include a specific focus on carbon emissions and peatlands.

Box 11 discusses Indonesia's Spatial Data Infrastructure and Box 12 introduces the concept of High Conservation-Value Forest.

#### Indonesia's Spatial Data Infrastructure (SDI)

Good planning is impossible without high-quality data, broad sharing of data, and transparency. Indonesia is making an effort to address these challenges through the development of a Spatial Data Infrastructure (SDI). The Ministry of Forestry is leading on the data management for the Forest Estate through development of the Forest Resource Information System. There are currently several pilots of the SDI, but all are located in Java. Berau Government, TNC, and partners have been exploring the potential for an SDI pilot as part of BFCP.

#### **High Conservation-Value Forest**

The concept of High Conservation Value Forest (HCVF) emerged as part of the Forest Stewardship Council (FSC) standard for forest management to guide the identification of areas with exceptionally important social, cultural, or environmental value and to implement a system of management and monitoring to guarantee that this value would be maintained or enhanced.

Today, HCV is used for spatial planning in Indonesia at the national or provincial level, for guiding plantation development to minimize negative ecological and social effects from natural forest conversion. During the IUP or Izin Lokasi process, HCV areas are identified by developers in their submissions, and developers are required to set aside and protect HCV land as part of their permits. The Roundtable on Sustainable Palm Oil looks at compliance with HCV plans in assessing plantations for sustainability certification. Banks consider plantations' records here as part of due diligence to assess loan requests.

#### **MRV AND CARBON ACCOUNTING**

National MRV standards and systems are likely to be a key components of a global deal on REDD and REDD+. East Kalimantan will need a technical support unit is needed to develop a basic MRV system for the province, and ensure that it is consistent with eventual national efforts. The MRV system will need to establish the province's baseline and create basic proxies for lowered carbon emissions (such as reduced deforestation), used to assess reduction efforts and to monitor impact. The need for such a system has already been established in the Norway-Indonesian Partnership, which is intended to make payments for verified emissions, in its later stages. Brazil's Amazon Fund, for example, already raises money on the basis of avoided deforestation achieved in the previous year. This performance is assessed against a moving average reference level of deforestation and certified by a technical committee of renowned scientists.

At present, there are a number of different methodologies for setting baselines and measuring avoided emissions for individual carbon projects in East Kalimantan. In order to reduce transaction costs and increase the likelihood of carbon projects attracting international carbon market payments for verified emission reductions and removal, it is critical that the provincial government incorporates methodologies that have already been independently verified, and establishes a province-wide approach. Ideally this approach contributes positively to the development of a national standard as well. Box 13 describes East Kalimantan's plan for developing a Measuring, Reporting, and Verification System (MRV).

**Box 13** 

## East Kalimantan's Plan for Developing a Measuring, Reporting, and Verification System (MRV)

Recognizing that the success of REDD+ implementation demonstration trials will be greatly affected by the reliability and international acceptance of the measuring, reporting, and verification system, the Provincial Government of East Kalimantan has begun an MRV development plan and will further strengthen it by:

- a. Regional Research and Development Agency (Balitbangda) cooperating with several competent parties: Forestry Faculty of Mulawarman University (especially Climate Change Research Center), Indonesian Center for Research and Development Dipterocarp Forestry Department develops monitoring/measuring emission system and carbon stock and determining provincial carbon data baseline.
- b. East Kalimantan REDD taskforce cooperating with international programs that develop REDD demonstration plots (at Malinau with GTZ Forclime, at Berau with GTZ Forclime and TNC, and at West Kutai district with WWF), the private sector (especially those holding both a Forest Plantation Wood Production Permit (IUPHHK) and a Wood Utilization Permit (IPK), and the district level REDD working group supplying data and field information.
- c. East Kalimantan Provincial Forestry Agency together with Regional Environmental Agency coordinating processes and development results of technical MRV at a regional level in order to syndicate, disseminate, and increase capacity among stakeholders as well as motivate local communities to participate.
- d. Regional Provincial Government and district or city governments across East Kalimantan, Governor, Bupati/Walikota and legislative parties (DPRD) supporting a regulatory policy that will enable the development and implementation of REDD to run smoothly.
- e. To ensure the implementation of MRV as part of climate change programs (such as mitigation, adaptation, and REDD projects), MRV will be inserted as a vital part of regional environment development plan and included in development discussions from village level (Musbangdes) up to national.

#### Carbon Accounting, Standards, and Rights in BFCP

Carbon accounting for the BFCP is being designed with the intent of generating verified emissions reductions (VERs) against a district-wide baseline for a future compliance market, as part of an anticipated post-2012 climate treaty framework. As with the Noel Kempff project in Bolivia, which pioneered accounting methods that both anticipated and formed the precedent for verification within a voluntary market, BFCP is pioneering and developing a precedent for the verification of compliance grade VERs within a post-2012 international climate agreement.

Carbon standards: Since the accounting methods for verification within a future REDD+ mechanism are not yet known, the BFCP will follow a rigorous interpretation of the Voluntary Carbon Standard (VCS), the most advanced and recognized carbon accounting standard available. The approach being implemented uses methods consistent with the IPCC Good Practice Guidelines and the GOFC-GOLD Sourcebook (GOFC-GOLD, 2009). Given that the VCS is designed for projectscale carbon accounting, as opposed to sub-national program scale accounting, or national-scale accounting, BFCP will also advance methods for nesting carbon accounting within provincial and national scales.

Aggregating carbon rights: Carbon rights for the forest estate in Berau will be bundled under the authority of a Ministerial Decree from the Minister of Forestry. Carbon rights from the "non-forest" land will be bundled under the authority of a decree from the Bupati of Berau. Through these decrees, all forest carbon rights will vest under the BFCP Supervisory Council.

#### **COMMUNITY ENGAGEMENT**

East Kalimantan's Environmentally Sustainable Development Strategy can only be implemented if it is actively supported by stakeholder involvement in key areas, such as land use, technology adoption, and behavior change. Such support can be achieved by a continuous, transparent, and participative process through which the government and its agencies involve communities in the decision-making process. Organizations of all types, i.e., government agencies, non-profit organizations, or private companies, have deployed community engagement programs in East Kalimantan.

East Kalimantan can build on two existing government-run community engagement programs in implementing this strategy: the musrenbang process and PNPM. The

musrenbang process is a bottom-up community engagement and development process whereby each village outlines its development priorities and submits them to the district. These are then rolled into a district plan, which is submitted to the provincial government for funding. The BAPPENAS-managed PNPM is another example of a program that is being used to support sustainable development. Recently, through technical assistance from the World Bank, PNPM has earmarked funds to support natural resource management and renewable energy schemes. The program, entitled Green PNPM, has recently been piloted in Sulawesi with plans to expand to all the sub-districts *(kecamatans)* in which PNPM operates. A large component of Green PNPM's funding is currently being deployed to support rural electrification through the development of micro-hydro power plants.

Private companies also need to have community engagement plans to promote behavioral change toward sustainable practices. (See Box 15 for a discussion on community engagement in the Berau Forest Carbon Program and Table 4 for some examples of initiatives that require community support.) PT Kendilo Coal Indonesia, as an example, built strong partnerships with local NGOs as it planned its mine closure. Working with these partners, it looked beyond narrow environmental rehabilitation to promote sustainable development of the local community. The closure plan

#### **Box 14**

included programs to provide employees and local people with new skills, in anticipation of the time when the company would no longer be the economic engine of the community. These included training focused on the set up of mechanical workshops for cars and motorcycles, sewing services, small trading shops, and various farming endeavors, improved agricultural practices (beyond slash and burn), and new cash crops for trading.

#### Box 15 Community Engagement in the Berau Forest Carbon Program

TNC and its partners have been working with forest communities in Berau since 2002 and recently completed a study of 20 of the 107 villages in preparation for the BFCP. Villages in Berau vary widely in level of forest dependence, remoteness, level of cultural homogeneity, and experience with the market economy. Virtually all villages are in a process of transition in livelihood strategies and governance institutions, and in most cases village institutions are ineffective, particularly in the upland high forest areas. Land tenure is not formally recognized, and villages are not often not even included in district spatial and development plans. Many villages are located within timber and oil palm concession areas, and each has or will be affected by timber, oil palm, or mining concessions. Proximity and weakly-defined property rights often lead to latent or overt conflicts between communities and neighboring companies. Key issues in community-company relations include consent of community fees and compensation to communities for use of the forest, and legally required investments by companies in community development.

The BFCP has identified six objectives for its community engagement plan:

- 1. **Involvement in low-carbon development strategy:** Meaningfully involve communities in design and oversight of Berau's low carbon development strategy. Forest communities are constructively engaged in BFCP governance and decision making at strategic and operational levels, as well as other important policy dialogs in Berau.
- 2. Free, prior, and informed consent: Ensure informed consent for all agreements, to be implemented on a sustainable basis.
- **3. Strengthened village institutions:** Help villages develop better governance institutions, ones that will allow for effective community involvement in natural resource management and sustained implementation of BFCP.
- **4.** Livelihoods: Improve livelihoods, including alternative livelihoods that reduce pressure on the environment in the short, medium, and longer terms.
- **5. Benefit sharing:** Establish arrangements for fairly and sustainably apportioned streams of benefits for villages including women, (social services, community infrastructure, etc.)
- **6.** Learning: Document and disseminate learning and scaling-up mechanisms from BFCP's community involvement component.

### Public awareness on climate change is also required in addition to community

**engagement programs focused on achieving projects.** In 2001, East Kalimantan took part in the survey Knowledge, Attitudes, and Practices: Natural Resources Management, which was a comprehensive survey of awareness and attitudes toward environmental issues. Although quite some time has passed since the survey, its findings indicated that while environmental issues are relatively important to residents of East Kalimantan, there was a gap to people becoming actively involved in solutions. Public awareness and engagement can be even more important and challenging for climate change as its impact is not as clearly or immediately seen as that for poor environmental practices (such as water or air pollution). Kaltim Green and the Governor have been recently conducting a larger public awareness campaign on climate change, which has included

EXAMPLE INITIATIVES REQUIRING COMMUNITY ENGAGEMENT SUPPORT		
Initiative	Community engagement required	
Use of degraded land	Recognition of community rights and existing land tenure in degraded land area; agreement on compensation paid to communities in area	
Zero burning policy	Education of impact of use of fires; training and technology on alternative land clearing methods; support for community based fire brigades	
Improved smallholder productivity	Provision of seedlings, training on the application of fertilizer, and techniques for planting, etc.	
Mining reclamation and rehabilitation	Best practices related to efficient, safe, and more environmental friendly mining operations, and post-mining land use	
REDD	Training of forest management techniques with a focus on education principles and tools for baselining and monitoring, reporting, and verification	
Water management	Education on impact of use of drainage for peatland decomposition; training and provision of technology for water management	

Green programs in various provincial ministries, conferences with business associations, public afforestation programs like "One man, five trees," and public events such as city biking events to promote alternative transportation.

#### **FINANCING**

Three finance-related functions will be critical to the success of East Kalimantan's environmentally sustainable development strategy. First, it is crucial to attract domestic and international financing to support East Kalimantan's abatement initiatives. Second, revenue-sharing models will need to be established to allocate funds to various stakeholders (including national, provincial, and district level governments, as well as project developers, communities, and individuals). Third, finances must be managed and distributed among these parties in a fair and transparent manner. Good governance of this highly complex flow of funds is one of the greatest challenges for REDD and REDD+ systems, and East Kalimantan will benefit from an investment in developing the best possible system here.

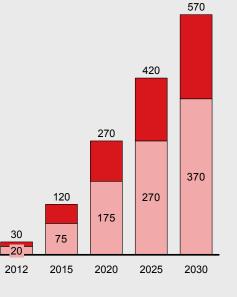

East Kalimantan will require significant, near-term international support to succeed in its plans to create low-carbon prosperity (EXHIBIT 75). In 2012, for example, between USD 20 million and USD 30 million will be required to launch pilots and start abatement initiatives. These costs will ramp up as the environmentally sustainable development plan expands and more initiatives are launched and on a larger scale. By 2030, ongoing running costs to support implementation of carbon abatement and sustainable livelihood opportunities will reach between USD 370 million and USD 570 million. Although the overall required funding is substantial, the cost per tCO2e abated is relatively low; the full abatement cost per tCO2e abated (including implementation costs) ranges between USD 2.00 and 3.10.

East Kalimantan cannot wait for funds from international carbon markets to realize its ambitious emission reduction objectives through to 2030. In the short term, interim funding from sources such as the Forest Carbon Partnership Facility (FCPF), the UN-REDD program, and bilateral programs such as the Indonesia-Norway Climate Change partnership will be critical to supporting East Kalimantan's efforts to establish its REDD readiness. The Informal Working Group on Interim

#### Exhibit 75

#### Required financial support increases over time

Total estimated annual costs USD millions per year (2010-2030)

Aggressive estimate

#### Three types of costs are included:

- Technical costs which are the costs to install the appropriate low-emission technology for an initiative (e.g. fire brigades, relocation costs to degraded land)
- Implementation costs are the costs needed to support implementation of a specific initiative (e.g. mining monitoring unit to enforce reclamation, training on reduced impact logging techniques)
- General enablers include the costs that are not specific to any one initiative but required for overall readiness to implement the strategy (e.g. enhanced spatial planning, MRV baseline)

SOURCE: Team analysis

Financing for REDD+ (IWG-IFR) envisages a phased transition of funding, with REDD programs initially relying on grants to build institutional readiness, followed by payments for reduced emissions based on simple proxies (e.g., deforestation rates), and finally transitioning to an advanced monitoring system that would allow a well-governed international carbon market to fund verified emissions reductions.

The Ministry of Finance and the Ministry of Forestry, have already outlined some initial guidelines for REDD projects.<sup>25</sup> In further developing the revenue-sharing model, some key design principles should be considered:

Ensure local individuals and communities are incentivized: In order to support the behavioral change required for environmentally sustainable growth, communities concerned must see clear benefits. In the Juma Sustainable Reserve in Brazil, for example, individuals receive direct payments based on regular inspections of local forests (Box 16).<sup>26</sup> The payments should include incentives linked to input-based metrics (e.g., for building dams, planting trees), performance-based metrics (e.g., reducing fire outbreaks), and eventually outcomebased metrics (linked directly to GHG emissions or proxies for emissions). As so much of the decision-making power for land allocation currently resides at the district level and within local communities, these groups must directly benefit from these payments. Local communities, villages, and districts will need to be appropriately compensated to be willing to make the changes needed for a more programmatic approach to low-carbon growth. The Amazon Fund,

<sup>25</sup> In July 2009, the Indonesian Ministry of Forestry suggested a revenue-sharing model with allocations depending on the type of forest ownership or permit, ranging from 10–50 percent for the government, 20–70 percent for local communities, and 20–60 percent for developers.

<sup>26 &</sup>quot;The costs of REDD: lessons from Amazonas", illED briefing paper, November 2009.

for example, includes representatives from different levels of government in its decision-making process.

- Lay the foundation for sustainable livelihoods: It is important that financing for emissions reductions does not become a form of welfare, but rather creates a foundation to support environmentally sustainable development. For example, the Juma Sustainable Reserve allocates a portion of funds to support income-generating activities based on sustainable land and resource use (Box 16, Box 17).
- Create the right incentive structure and framework to engage the private sector: Private project developers will be critical to environmentally sustainable development, given their access to capital and the skills needed for detailed monitoring and project management. The World Bank convened a workshop in November 2008 where REDD project developers provided input on how to support REDD activities in Indonesia. Some of the recommendations included obtaining clarification from the national government on where authority lies for decisions on REDD implementation, helping to fast track the approval process for REDD projects, and providing clarity on whether avoided deforestation carbon credits (VERs) require national government approval before being sold.<sup>27</sup> At present, land usage decisions are split between the Ministry of Forestry, local governments, and community groups. The provincial government could help facilitate a more integrated process and ensure that the concerns of the private sector operators are addressed.

#### **Brazil's Amazon Fund**

The Amazon Fund, created in August 2008 by the Brazilian Government, mobilizes international funding to combat deforestation. The Amazon Fund operates on a donation basis, raising money on the basis of avoided deforestation achieved in the previous year. Performance is assessed against a moving average reference level of deforestation, adjusted every five years. A Technical Committee with six renowned scientists certifies the emission reductions claimed.

Managed by BNDES, Brazil's Economic and Social National Development Bank, the fund grants funding to projects that contribute to the prevention of deforestation as well as to the conservation and sustainable use of the Amazon biome. A multi-stakeholder committee, organized in a three-chamber system with representatives of local government, national ministries, and civil society (including indigenous peoples, traditional communities, NGOs, industry, and scientists), determines funding allocations. Decisions are taken on the positive vote of all three chambers.

Once the revenue-sharing model is defined, there needs to be a method of allocating funds to the various recipients that complies with basic standards for efficiency, fiduciary oversight, and transparency. Recognizing the critical importance of maintaining the integrity in its operations, Aceh's BRR used a combination of internal audits (carried out by BRR's internal audit team as well as the Financial and Development Supervisory Agency), anti-corruption initiatives (carried out by BRR's Anti-Corruption Unit), external audits (carried out by the Supreme Audit Agency), and public disclosure of financial flows (BRR regularly opened the agency's balance sheet to the public, for example) as well as making all employees sign an "Integrity Pact", which included forbidding employees from receiving any compensation beyond their agreed-upon market salary.<sup>28</sup>

For those funds earmarked for local communities and individuals, there are some existing successful financial distribution platforms, such as Indonesia's Planning Department's (Bappenas)

#### Box 16

<sup>27 &</sup>quot;Report on Implementation of a Learning Workshop: Developing a Market for REDD in Indonesia," World Bank, January 2009.

<sup>28 &</sup>quot;Finance - Seven Keys to Effective Aid Management", BRR NAD-NIAS, April 2009.

PNPM program, which could be potentially augmented and refined to distribute these funds. Funds could initially be allocated at the community level, but potentially gradually evolve to be allocated to individuals, similar to Brazil's Juma Sustainable Development Reserve.

#### **IMPLEMENTATION**

This analysis represents just the first step to achieving environmentally sustainable development. We see momentum developing through three phases.

**Phase 1 - Define the Environmentally Sustainable Development Strategy:** The first step is to develop an environmentally sustainable development strategy (as summarized in this report) that identifies the major opportunities for abatement and new sector growth, the critical actions required for success, and an estimate of the associated costs. This strategy then will be circulated to experts, community representatives, and other interested parties in all districts as part of an extensive process of integration, socialization and refinement to reconcile the priorities emerging from high-level analysis with the priorities that our communities feel on the ground.

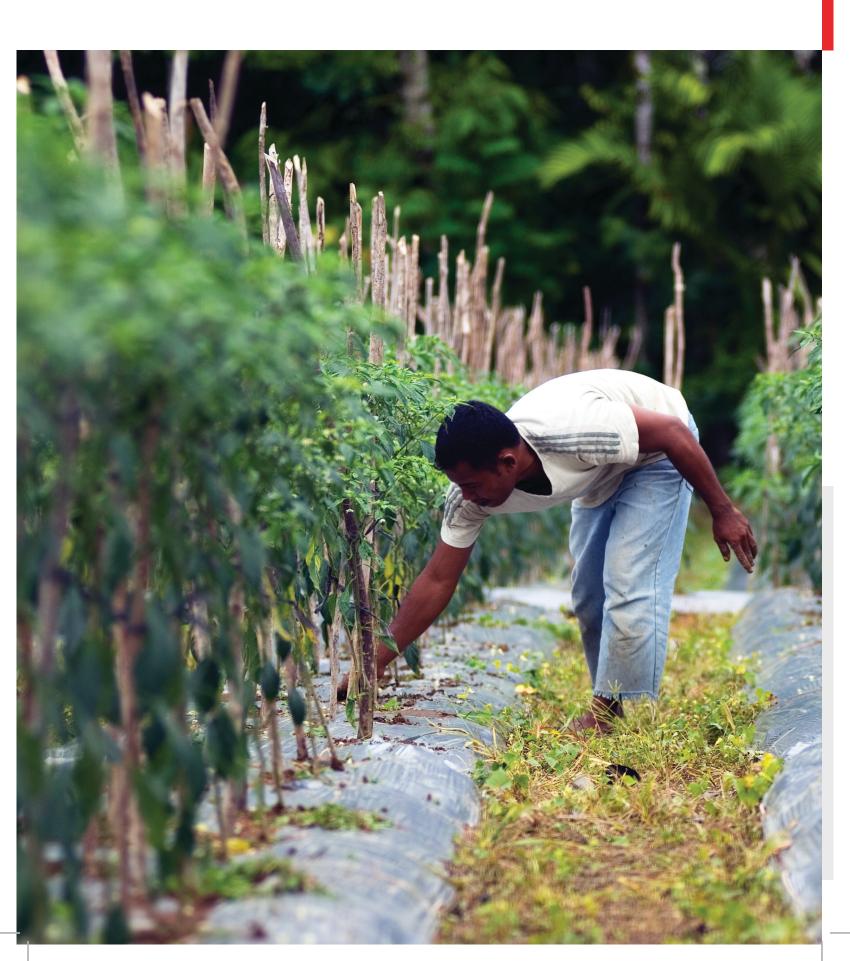

**Phase 2 - Develop basic readiness structures:** The next phase requires the development of the basic architecture needed to attract international financing and support sustainable development. This includes finalizing the organizational design of the "green" delivery unit (including establishing reporting and decision-making processes), working with district pilots to prepare initiatives, and begin to build critical enablers such as enhanced spatial planning and MRV baselines.

**Phase 3 - Pilot environmentally sustainable development initiatives:** This phase will launch an initial pilot program to support an approach to sustainable growth that focuses on the prioritized opportunities for abatement and new growth sectors. Following the pilot and a review of the lessons learned, it is envisaged that there would be a progressive rollout to other districts, with the eventual transition to a province-wide approach.

Our analysis tells us that we can achieve growth and cut our carbon emissions. Our experience warns us that this is difficult, but also gives us faith that much can be achieved, as we look at our province's record of development over the last decades.

East Kalimantan is a highly diverse society, as befits the richness and variety of our natural environment, from our forests and mountains to our seashores along the trading routes of Southeast Asia. To develop, we must unleash the drive and creativity of all members of our society. Environmentally sustainable development means that this creativity and drive will be built on a foundation of respect for our god-given natural heritage.

Implementation and enablers | 119

# Appendix

## SYNDICATION ROADSHOW

#### Introduction and context

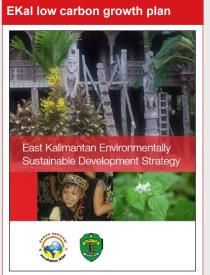

Some 78 percent of Indonesia's emissions today derive from land use, land-use change, and forestry (LULUCF) and peatland. Today, Indonesia is the world's third largest emitter of CO2e emissions at 2.1 GtCO2e of emissions annually. Reducing these emissions will be a challenging task, and indeed, there is already a strong urgency for Indonesia and similarly for East Kalimantan to adapt and execute a workable low carbon economic development strategy to preserve forest area and reduce emissions from deforestation and forest degradation while at the same time maintain economic development.

In May 2010, Indonesia finalized an agreement with Norway to secure USD 1 billion in donor funding, which is to be spent towards readying Indonesia for REDD implementation and financing a pipeline of emission abatement initiatives. If the agreement is successfully implemented, it would result in setting up the necessary institutional framework to enable REDD+ and, with that, mechanisms to remunerate local governments and even individual operators and communities for activities that result in avoided emissions within the forest sector. Setting up this framework is key to allowing flows of international funds for verified carbon payments and ensuring long-term sustainability of abatement initiatives in the forest sector in Indonesia.

East Kalimantan is among the three largest emitters in Indonesia together with the provinces of Central Kalimantan and Riau. Under the leadership of Governor Dr. Awang Faroek Ishak the province has now started to address the environmentally unsustainable development path of East Kalimantan (Exhibit 76).

#### East Kalimantan growth plan follows a unique approach

#### Exhibit 76

#### Key elements

Sustainable economic development strategy

- Competitive strengths and weaknesses
- New sources of growth

#### Sector strategies

- Palm oil, forestry, agriculture, coal, oil & gas
- Abatement opportunities, pilot projects, required policy changes

#### District strategies

- District's size and land use
- Emissions and abatement potential
- GDP and employment

#### Implementation and enablers

- Critical enablers required
- Estimate of total costs

Projected emissions for East Kalimantan are expected to grow at 1.2 percent annually from 251 MtCO2e in 2010 to 331 MtCO2e by 2030, representing some 11 percent of Indonesia's total current emissions. Following a low carbon development path could potentially lead to an annual emission of 134 MtCO2e, a 60 percent reduction by 2030 against a BAU scenario, primarily from abatement initiatives within the agriculture, oil palm, and forest sectors (exhibit below). Despite the perceived inhibitive nature of low carbon initiatives to economic growth, following such a path is not expected to decrease the real GDP growth of the province. Instead the GDP growth between 2010 and 2030 is expected to increase from 3 percent to 5 percent under such a scenario when compared to business as usual, as low carbon development paves the way towards improved efficiency, yield, and productivity from the same finite resources presently available.

There is still an overall skepticism among Indonesians towards REDD+, more specifically, the notion of making and receiving payments for activities that result in reduced deforestation and forest degradation. The majority of local stakeholders that we engaged with at the provincial and district levels strongly feel that deliberate actions to reduce deforestation will necessarily come at the expense of development. This level of skepticism is not uncalled for. On the one hand development in Indonesia has often come at the direct expense of a net reduction in forest cover and, on the other hand, there has been only very limited success in executing pay for performance payments anywhere in the world. As a consequence, progress towards setting up a workable REDD+ framework has been much slower than expected, not just in Indonesia but also the rest of the world. Whatever the outcome of global REDD+ related discussions and decisions may be, we must move quickly to do what we can to support preservation of our remaining forest resources.

The East Kalimantan government believes that a first step towards defining a workable solution is to convince relevant stakeholders of the following:

- There are many potential initiatives that fit the dual objective of reducing emissions whilst also supporting economic growth. There are many examples of initiatives East Kalimantan can undertake in the near term that fit this criteria these include using degraded land for oil palm expansion, expediting the development of coal bed methane (CBM), improving crude palm oil (CPO) yield from palm oil smallholders, and developing value adding downstream operations in the forest and agribusiness sectors that source the raw materials they require from sustainable sources. Economic development will not be inhibited; however there will be safeguards to protect the environment and finite resources with further upside in the form of carbon payments for reduced emissions.
- Payments for verified carbon abatement are complex mechanisms that require thorough foresight and preparation. REDD+ ideally necessitates, amongst other requirements: 1) a systems to monitor, report, and verify (MRV) carbon stock within a given area; 2) a mechanism provinces, district, and communities to receive donor funding; 3) safeguards and mechanisms of enforcement in place to ensure adherence to regulations and planning decisions, and 4) a pipeline of funding-ready projects that have exhibited clear viability as a means of CO2e reduction and required upfront investments. East Kalimantan is not alone in lacking mechanisms along all four of these dimensions, so is the rest of the world, including, in fact, the majority of potential donor countries. This should not deter us from accepting the challenge. Instead, it is with clear realization of such difficulties ahead that East Kalimantan is preparing itself by making progress along these fronts.
- There is an urgency to move quickly. It should be unsurprising that the interest in REDD+ is high, as the forest sector could deliver 15 to 20 percent of global abatement needed at abatement cost magnitudes lower than other alternatives, e.g., abatement within the power generation, energy consumption, and transportation sectors. Yet the cost will also be high. It is estimated that in order to significantly contribute towards reducing the impact of increasing CO2 levels on climate change, REDD+ will require a global allocated fund of USD 20–35 billion over the 2010–2015 period. Today, Norway, USA, Japan, Germany, UK, France, Netherlands,

and Australia have already committed significant funds towards REDD+ over the 2010-2015 period. As a major owner of carbon rich primary and secondary forests, East Kalimantan is in a favorable position for such funds; we however need to move fast to become early recipients and convert the growing interest from these countries into tangible funds at the ground level.

#### **District roadshow**

The distribution of political power across Indonesia's different government levels necessitates that environmentally sustainable development initiatives are best instigated from the bottom up at the district level and not dictated via top-down directives. To kick-start such initiatives, the government of East Kalimantan, together with the national DNPI and other partner organizations, decided to conduct a set of workshops in each of the 14 districts. The objective was to share our intentions to shift to a low carbon pathway and kick-off the early preparation for specific, district based low carbon development initiatives.

As part of this early preparation to move towards REDD+ readiness, we created a Low Carbon Growth Strategy (LCGS), the findings of which we discussed with district participants over the course of the roadshows in the spirit of seeking feedback that would highlight any shortcomings and the possible need for improvement before final publication.

After having concluded a draft of the LCGS report in September 2010, roadshow workshops were held between September 20, 2010 and October 28, 2010 in each of the 14 districts. The following section of this report aims to articulate the feedback and findings from the workshops to district authorities and also to the central government, particularly the newly founded REDD+ agency that is in the process of selecting a pilot province for early implementation of a nationwide REDD framework.

#### **Objectives**

Generally, the workshops at the district level had five primary objectives:

- Increase the level of understanding of East Kalimantan's environmentally sustainable development strategy and plans. The 14 districts across the province are at various starting points, both economically and environmentally, and also in their understanding of low carbon growth. There is a need to ensure that each district fully understands the need for East Kalimantan to commit to an environmentally sustainable development pathway for the future. Of all districts, Berau is the most advanced in implementing a workable REDD readiness framework as a results of ongoing efforts from the local government and its development partners TNC and GTZ.
- Discuss findings of analyses presented within the LCGS report, particularly those relevant at the district level. Detailed analyses were carried out during the development of the LCGS to determine emissions and abatement scenarios down to the district level. These findings should help inform district administrations in identifying the most viable and cost efficient emission reduction initiatives that can be captured in the near term
- Draw on input and feedback from the districts in the spirit of further refining the accuracy and improving the impact created by the LCGS report. Despite having communicated and collaborated extensively with district level representatives during the drafting of the report via one-on-one discussions and workshops, we naturally need to make a final reconciliation of any possible differences between data sources in order to provide the most accurate representation of the analysis within normal limits of error
- Get support from districts to the coordinating role of the provincial government within the provincial and national climate change stakeholder community. The development of the LCGS is only one part of our broader role to translate national level plans and strategies to reduce emissions into clear guidelines and actions at the ground level. The roadshows serve

as a starting point for a two-way channel for dialog between district and province so as to better align stakeholders and improve overall coordination

Collect ideas for potential emission reduction pilot projects at district level, in line with a longer term objective to shift to a strategy of low carbon development. Pilot projects not only serve as a means to test and showcase the viability of any one initiative, they also help the central, provincial, and district governments to uncover gaps in the supporting environment, for example, pointing out the need for a revision to current policy or regulation. It is therefore important that pilot projects are started as early as possible in order to inform the most optimal decisions

#### Approach

Prior to the roadshow workshops, an invitation letter was sent from the Governors office to notify all invited participants of the agenda and the date of each district workshop. In addition, the letter also included:

- A list of key topics for discussion
- Summary of issues within each topic for deliberation during the workshop
- Related parties advised to attend, which included:
  - All relevant government departments, e.g., Environmental Agency (BLH), District-level Forestry Authority (Dinas Kehutanan), District Land Planning Agency (Bappeda), Districtlevel Estate Crops Authority (Dinas Perkebunan), District-level Mining and Energy Authority (Dinas Pertambangan dan Energi)
  - Non-government organizations (NGOs) namely TNC and WWF, forestry related working groups), industry associations, and academics (mainly from Universitas Mulawarman given its heavy emphasis on forestry research)
  - Private operators within the forestry, palm oil, mining, and oil and gas sectors, e.g., BP MIGAS, PT Badak

Before each session, the roadshow team (detailed further below), which consisted of a combination of representatives from the provincial Environmental Board (Badan Lingkungan Hidup, BLH) and non-government organizations (Pokja REDD, TNC, and WWF), and McKinsey & Company, conducted a meeting with the highest government official whom they managed to secure an audience with – the head of the district (Walikota or Bupati), or direct report (the Wakil Bupati), the district secretary (Sekda) or his/her direct assistant, or the head of the district level Environmental Board (BLH). This practice of convening a meeting proved helpful to communicate in a personal setting what the objectives of the workshop were in order to improve top level support of the importance of ensuring optimum attendance of all advised stakeholders.

#### Agenda

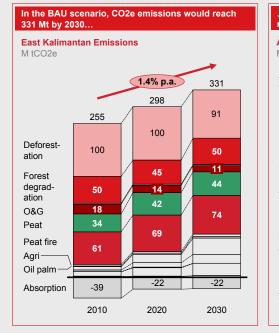

The common agenda for each workshop followed the following outline. In general, each session lasted approximately three hours.

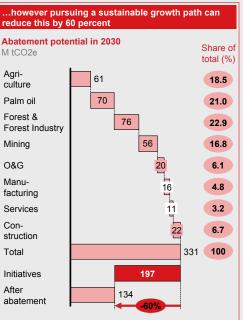

- 1. Discussion on the global climate change political debate, with focus on Indonesia's response to climate change via the letter of intent with Norway
- 2. East Kalimantan's journey towards a low carbon economic development pathway by presenting business-as-usual emissions and major abatement initiatives
- 3. District level breakdown of emissions with elaborated focus on major emission sources
- 4. District level emission reduction initiatives and low carbon economic development opportunities
- 5. Question and answer session, followed by open discussion on pilot ideas

#### **Presentation**

The exact presentation shared at each roadshow session varied, as the content was tailored for each district in order to better provide a specific picture of emissions and abatement opportunities. The following exhibits have been excerpted from the presentations to give the reader a brief sense of what was presented at each session.

#### BAU emissions in East Kalimantan will grow to 331 MtCO2e by 2030 pursuing a low carbon strategy can potentially reduce this by 60%

#### **Feedback and observations**

#### **General observations and feedback**

The roadshow team made some general observations of the district roadshows. The key ones are summarized as follows:

- District representatives were very welcoming to expanded provincial support in matters related to climate change, such as the conception of the LCGS report and organizing the roadshow workshops. Participants praised the efforts of the provincial government, e.g., through analyses such as the LCGS report and conducting forums such as the roadshow sessions they said it was through such channels that decision makers could be better convinced to make a change towards the better. Many also reinforced the need for us to continue the momentum created by the LCGS findings, against the background of the current Lol<sup>29</sup> with Norway, and begin to implement projects as articulated in the LCGS.
- There was a high level of enthusiasm amongst those in attendance at the workshops. Although a handful of people raised some questions on the methodology and exact figures used in the LCGS report, most very vocally said the report agreed with their own analysis and were very keen to move beyond figures and analysis towards action. As such there was in-depth discussion centered around pilot project ideas for each district.
- Opportunity to further educate the mass public on climate change. Many participants felt they had learned valuable insights from the discussion and analysis shared during the session, and that it would be beneficial if such findings were shared more broadly to the greater public. Much of the success of climate change initiatives hinge on creating greater awareness in society, for example by encouraging more efficient energy use, e.g., use of electrical appliances. Equally, such awareness also helps create societal pressure to politicians and governments to invoke change. The team also noted that in general, due to a lack of experience and exposure to carbon financing mechanisms (e.g., CDM<sup>30</sup>), many participants felt that low carbon initiatives would inherently and necessarily lead to a slowing of economic development. The lack of understanding is even more pronounced regarding the complexities required to implement a pay for performance carbon trading system under a REDD+ framework.
- Lack of clarity in the role of provincial coordination in climate change related initiatives. Participants were confused and even frustrated about initiatives, which have failed to rally the support, commitment, and alignment between district and province in climate change matters. Many suggested a more deliberated and permanent effort to bring initiatives under a single umbrella, e.g., a provincial level council for climate change – making communication, coordination, and support from the province much clearer to the districts
- Much confusion and many questions around the implication of the letter of intent between Indonesia and Norway. Most districts are concerned with the implications that a potential suspension of new forestry and agribusiness permits will bring to their development plans; even more were confused as to what actions were to be taken to better prepare themselves for changes under such an agreement. Very few saw the halting of deforestation stemming from the suspension of new permits in a positive light, citing that such a move would hinder growth and development. Even fewer still were confident that compensating payments would be made in return for the avoided deforestation – further emphasizing the need for the national REDD+ taskforce to better articulate and communicate the national plan for a REDD+ strategy to the public

<sup>29</sup> Letter of intend to reduce deforestation in Indonesia was signed between the two governments in May 2010

<sup>30</sup> Carbon payments under the Clean Development Mechanism scheme established under UNFCCC

- Degraded land is an appropriate substitute for oil palm expansion, however such land often has Kawasan Hutan (KBK<sup>31</sup>) status and is therefore outside of district purview. There are a lot of administrative procedures surrounding conversion of KBK into KBNK<sup>32</sup> (and vice versa). A smooth conversion process would be necessary for a successful swap mechanism between forested land slated for oil palm development with degraded land under central government administration. In East Kalimantan some 20 percent of kawasan hutan is already non-forested. It is important for districts to gain access to degraded land within the kawasan hutan to carry out swaps with local palm oil concession holders on forested land. Furthermore, participants mentioned that land tenure disputes were very common within districts, but rarely managed well by the relevant district, provincial or central government organizations. The central and provincial governments are said to have not done enough to resolve disputes quickly, thus creating a deterrent for companies to agree to land swaps. Districts would welcome assistance and collaboration with the province to smoothen such processes
- Unclear future of East Kalimantan's spatial plan. Apart from the noted concern that the current spatial plan for the 2010–2030 period has still not been approved, participants acknowledged the need for the plans to directly account for a low carbon economic development scenario under a moratorium or license suspension agreement, or more broadly under the 26 percent national emission reduction target that President Yudhoyono publicly announced in 2009. Furthermore, a few districts cited the lack of clear spatial planning guidelines from the provincial and central governments as well as a lack of analytical tools to assist as impediments to creating optimal spatial plans in line with low carbon development
- No shortage of pilot ideas among district participants. Most districts gave ample suggestions of pilot projects for their respective districts during the workshops. Some suggestions included sustainable forestry management, reduced impact logging, and ecotourism (Kutai Timur); development of coal bed methane and using waste for bioenergy production (Bontang); mine reclamation and reforestation of Mahakam Delta (Kutai Kartanegara); and suspension of recent and new coal mine concessions (Samarinda). However, the proposed initiatives varied greatly between districts, again, indicating the different levels of understanding and political commitment from each.

#### **District specific observations**

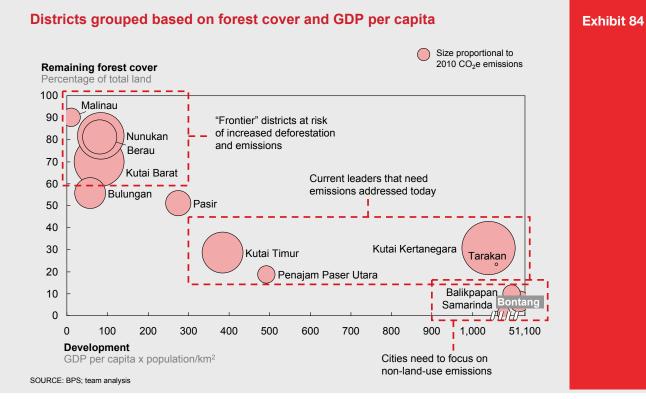

As the responses, feedback, and observation in each district were partly repetitive, we have grouped the districts based on forest cover and GDP per capita (see Exhibit) to strengthen the common messages from each.

- High remaining forest cover is a feature of the districts of Malinau (90 percent), Nunukan (82 percent), Berau (81 percent), Kutai Barat (70 percent), and Bulungan (56 percent), which are generally located in the north and west of the province. Facing the challenge of accelerating the pace of development, their spatial plans indicate they are moving towards a steep trajectory of deforestation.<sup>33</sup> During the workshops at these districts, the focus of discussion centered around the theme of stopping or reducing deforestation and other land use changes in relevant sectors, e.g., oil palm, agriculture, and forestry
- Medium to low forest cover is a feature of districts with 10–50 percent remaining forest cover: Paser (51 percent), Kutai Timur (29 percent), Penajam Paser Utara (19 percent), Kutai Kartanegara (31 percent), and Tarakan (23 percent). Deforestation through logging and land

<sup>31</sup> Forest estate under control of the national Ministry of Forestry

<sup>32</sup> Areas assigned for non-forest use under control of the district governments

<sup>33</sup> Under the original spatial plan, planned conversion from forest to non-forest status (KBK to KBNK) in overall East Kalimantan was 1.3M ha over the next 20 years – translating to an annual deforestation rate of roughly 150,000 ha. This rate of deforestation would likely maintain current BAU emissions from deforestation

conversion to oil palm and timber plantations may no longer be the primary driver of emissions within these districts; instead economic activities such as mining, oil and gas, power, and transportation are major contributors. Discussion during these workshop sessions generally covered the full spectrum of emission sources and abatement opportunities – both LULUCF<sup>34</sup> and non-LULUCF with specific sector focus based on what the analysis indicated

Little or no forest cover is generally found in the city (Kota) districts, i.e., Balikpapan (10 percent), Samarinda (1 percent), and Bontang (6 percent), where primary emitting sectors are generally the non-LULUCF sectors of oil and gas, power production, and transportation. The discussions held at these district roadshows were tailored to focus towards major sources of emissions, e.g., LNG refining operations in Bontang, and power consumption and public and private transportation in and around Samarinda and Balikpapan.

#### Districts with high remaining forest cover

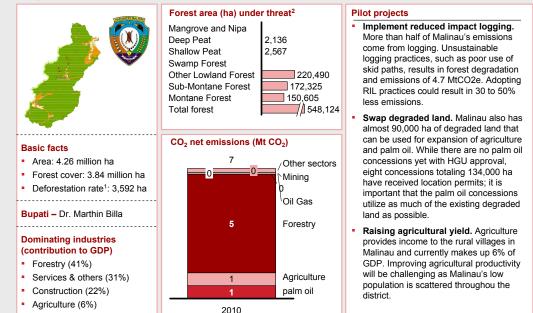

**Malinau** holds the largest remaining natural forests in East Kalimantan (3.8M ha) and has retained the most forest cover at 90 percent. Malinau can claim the smallest loss of forest of any district from 2003 to 2008, at just 4,000 ha per year. Unsustainable logging practices however, such as poor use of skidding trails, result in significant forest degradation and annual emissions of 4.7 MtCO2e. With no oil, gas, or coal reserves, Malinau's economy depends on forestry, agriculture, and the not yet developed service sector.

The workshop at Malinau was chaired by the Assistant II, and attendance was low, at only 15 people. The primary feedback during the session was the need for tangible incentives to be provided to farmers to enable mechanical land clearing instead of using fire, which often results in uncontrolled burning, as well as a request for clarity from central and provincial governments on the funding mechanism for reforestation activities.

<sup>34</sup> Land use, land use change, and forestry

1 Average deforestation rate 2004 to 2008 2 Under the proposed RTRWP 2008 to 2017

SOURCE: BPS Kaltim, Daemeter Consulting, EKal low carbon growth plan, WWF team analysis

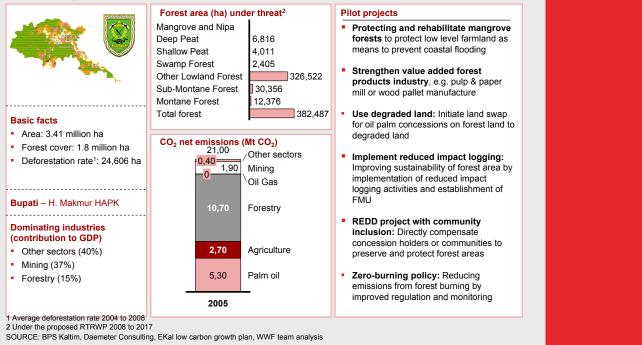

SOURCE: BPS Kaltim, Daemeter Consulting, EKal low carbon growth plan, WWF team analysis

**Nunukan** is the largest district at East Kalimantan's northern border (1.43M ha) and has abundant forests and peatland. The district retains much of its forest cover, more than 80 percent. Nunukan has substantial peatlands, at 180,000 ha, more than any other district. Smallholder fires spread across degraded peatlands, resulting in annual emissions of approximately 16 MtCO2e.

Attendance at the workshop, chaired by the Assistant II, was relatively good at 30 participants. Participants cited that the slow progress of climate change initiatives across Indonesia was due to lack of commitment, poor attitude, and weak regulation and enforcement by the central, provincial and district governments. They welcomed provincial assistance in tackling the emissions risk from peatlands and specifically requested enabling legislation that would deter the expansion of palm oil onto the last remaining intact peatlands of East Kalimantan.

## Berau: It is expected that conversion of forests in other land use will remain high under a business-as-usual scenario

Exhibit 87

**Berau** is still more than 60 percent covered by forest. Fourteen logging companies hold over 880,000 ha in production forest concessions, and three companies hold 60,000 ha in HTI<sup>35</sup> concessions; in total they cover nearly 40 percent of the land area. Still, large expanses of standing forest and a relatively high level of readiness due to the initiatives from TNC and GTZ make Berau attractive as a district wide REDD demonstration area.

There are already initiatives to ensure adaptation of sustainable timber forest practices in current production forests (Hak Pengusahaan Hutan, HPH). Such an initiative is an extension of the reduced impact logging concept, and the district welcomes further support to ensure such practices are adapted – see box below. District participants are receptive to the idea of expanding HTIs to revitalize the currently idled Kertani Kertas pulp mill and grow oil palm on degraded land, however they cited issues surrounding the difficulty to move such lands from current KBK status.

<sup>35</sup> Hutan Tanaman Industri (timber plantations for industrial use)

#### Berau forest carbon program by TNC

The vision is an integrated district-scale forest carbon program that, by 2015, brings at least 800,000 ha under effective management, avoids emissions of 10 million tons of carbon dioxide over five years, protects critical watersheds and areas of high biodiversity value (including habitat of 1,500 orangutans), and creates improved economic outcomes and opportunities for communities living near forests.

The Berau Forest Carbon Program — a partnership between national, provincial and district governments, civil society, and the private sector — aims to enable Berau to meet its development goals while sustainably managing its forests by developing a carbon finance mechanism that delivers effective incentives to reduce emissions from forest loss. In this effort, Berau offers a meaningful learning opportunity for how the concept of Reducing Emissions from Deforestation and Forest Degradation (REDD) can be applied across an entire political jurisdiction that is large and complex enough to bridge the gap between small, isolated emission-reduction projects and nation-wide REDD programs, thereby providing important lessons to support development of a REDD program across Indonesia

The Berau Forest Carbon Program can shed light for policy makers on the institutional structures that will need to be in place for national REDD programs to be implemented in countries participating in an international REDD mechanism. UN-level negotiations could benefit from an intensively documented example that uses real data and circumstances on the ground to illustrate what it will take to successfully deliver REDD across entire tropical forest states or countries. Given the Indonesian government's action at the national level, and strong linkages between Berau and these national processes, the Berau Forest Carbon Program is well poised to serve as this example.

The first step in realizing this vision is to build the capacity and institutions to support sustainable land use planning, carbon accounting, and community involvement programs, among others, that are well integrated with existing government operations. This institutional readiness will be paired with model, site-level emissions reduction activities, such as reduced impact logging, oil palm swaps, and improved management of protected forests, that can be scaled up as forest carbon markets become operational. Such investments will enable Berau and Indonesia to be ready to participate when the future carbon market emerges.

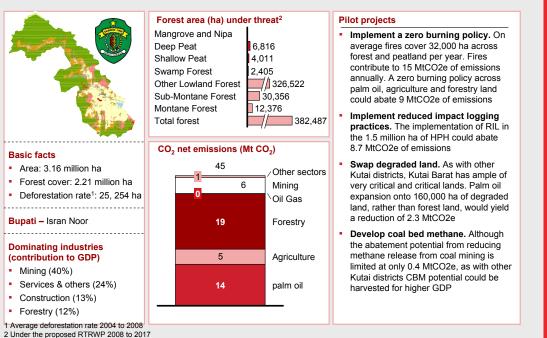

**Kutai Barat's** economy is driven by mining and forestry, contributing 40 percent of the district's GDP. Forestry contributes 12 percent of GDP from the 1.5 million ha of HPH concessions and 156,000 ha of HTI concessions. Palm oil is set for a rapid expansion from the current 90,000 ha with operating licenses to the 450,000 ha, based on currently issued location permits.

Four people attended the Kutai Barat workshop chaired by the Deputy Head of BLH, due to it coinciding with Hari Sumpah Pemuda and the birthday of the district.

Participants in the workshop were most involved during the discussion about reduced impact logging and how all companies operating in the district could implement it. District government officials recognize the importance of forest preservation to local Dayak communities in the district. For these communities, forest is more than just woods, leaves, and animals. Forests are also a home and source of life, where Dayak tribes stay and harvest various forestry products for their own consumption. Therefore, the team's suggestion to implement reduced impact logging practices across the district was well received, as many new companies are said to be vying for HPHs in this district. It was suggested during the discussion that reduced impact logging practices should be required for every company before it is allowed to operate in this district. The government together with the NGOs has agreed to develop and monitor a certification process related to this issue.

#### Kutai Barat: High deforestation pathway will remain in the future

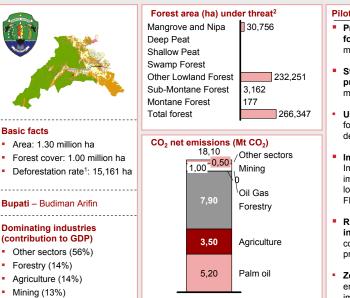

#### Exhibit 88

#### Bulungan: deforestation rate is expected to remain at historical levels

Exhibit 89

#### Pilot projects

- Protecting and rehabilitate mangrove forests to protect low level farmland as means to prevent coastal flooding
- Strengthen value added forest products industry, e.g. pulp & paper mill or wood pallet manufacture
- Use degraded land: Initiate land swap for oil palm concessions on forest land to degraded land
- Implement reduced impact logging: Improving sustainability of forest area by implementation of reduced impact logging activities and establishment of FMU
- **REDD** project with community inclusion: Directly compensate concession holders or communities to preserve and protect forest areas
- Zero-burning policy: Reducing emissions from forest burning by improved regulation and monitoring

SOURCE: BPS Kaltim, Daemeter Consulting, EKal low carbon growth plan, WWF team analysis

2005

To avoid illegal forest practices, it was also suggested by participants that indigenous Dayaks should be engaged to monitor activities in the forests. Given the high numbers of Dayaks in the population, they could help promote sustainable forest development through their customary traditions of lembo.<sup>36</sup>

Finally, participants also agreed that Kutai Barat should continue to reinforce existing national legislation that was ratified by the national parliament in 2003, whereby any party who exploits or cuts down one tree in Kutai Barat district is obliged to plant three new trees as replacement.

**Bulungan's** emissions stem from deforestation and forest degradation caused by unsustainable levels of timber harvesting in its five HPH concession areas totaling over 560,000 ha. Bulungan's 1 million ha of forest are being deforested at 15,000 ha p.a. driven by the expansion of palm oil and agriculture resulting on emissions of more than 12 Mt CO2 from deforestation alone. The district's 80,000 ha of peatland are also at risk of being opened.

Attendance at the roadshow was good at approximately 30 participants, chaired by the District Secretary (Sekda). Representatives from neighboring district, Tana Tidung, were invited to attend the same session, due to their close proximity; however, none did. The Ministry of Forestry of Bulungan has implemented several initiatives towards forest rehabilitation, including creating a working group to counter illegal logging. The district highlighted the need for a structured incentive mechanism for forest protection initiatives, e.g., pre-allocating financing via district budget (Anggaran Pendapatan dan Belanja Daerah, APBD<sup>37</sup>).

Neighboring district, **Tana Tidung** was just recently founded and is expected to face similar issues as Bulungan.

#### Districts with medium to low forest cover

**Paser.** Two-thirds of Paser's GDP comes from coal mining, agriculture, and estate crops (mainly palm oil). The district still retains 50 percent forest cover, mainly in its mountainous interior. Land devoted to palm oil is expanding, from 95,000 ha with HGU<sup>38</sup> licenses to a potential 267,000 ha with lzin Lokasi,<sup>39</sup> resulting in annual emissions from deforestation of 2.1 MtCO2e. Unsustainable logging practices in those areas produce annual emissions of 2.4 MtCO2e from its 197,000 ha of HPH.

The affiliation of participants at the Paser workshop was considerably diverse. It included industry participants, e.g., Kideco (the largest coal mine operation in the district), local media (district's newspaper representative), academia, and a representative of the local parliament, Dewan Perwakilan Rakyat Daerah (DPRD). The entire session was chaired by the district Sekda.

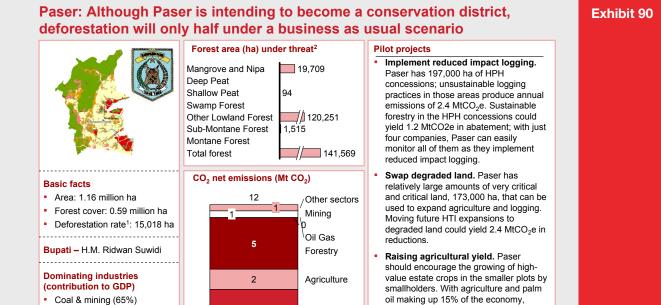

One specific complaint from participants concerned the autonomy of central government to give out timber concessions without scrutiny or approval from the district. In theory, if sustainably carried out, such activity would not degrade forest in the longer term; however in reality timber operations result in greater deforestation and forest degradation than agriculture and estate crops. Furthermore, it was said that some of these concessions are automatically renewed upon expiry, again without district consent.

<sup>36 &</sup>quot;Lembo" is traditional Dayak culture to maintain forest together as a community. This culture involves communal supervision of forests and cultivation of forestry products that do not harm trees (e.g., harvesting honey, growing cassava). This culture was once adopted across Kalimantan by all Dayak tribes, but has long been forgotten because companies started to come in and buy lands from different Dayak tribes. If we promote this practice rigorously across Kutai Barat, we can easily get indigenous people to supervise forest areas (hence there would be no need to hire forest police) and improve the local economy by helping them to cultivate traditional forest products

<sup>37</sup> Anggaran Pendapatan dan Belanja Daerah (APBD) is the annual district budget agreed upon by the district House of Representatives at Province and District levels

<sup>38</sup> License to operate oil palm plantation

<sup>39</sup> Agribusiness location permit

palm oil

raising yields could improve GDP

significantly as well as rural incomes.

The government of Paser acknowledged that mining plays an important part in the district's economy. Therefore its fundamental concern in implementing mining-related pilot projects is the withdrawal of mining companies from the district. It was discussed in the workshop how such an event could be avoided through clear understanding and cooperation between the government and private mining companies; no concrete steps were suggested.

1 Average deforestation rate 2004 to 2008 2 Under the proposed RTRWP 2008 to 2017

Agriculture (9%)Estate crops (6%)

It was concluded at the end of the workshop that the next step for Paser is to enforce the existing land-use related regulations. Apparently the district government of Paser has recently ratified several such regulations; but its commitment to enforcement is yet to be shown in practice.

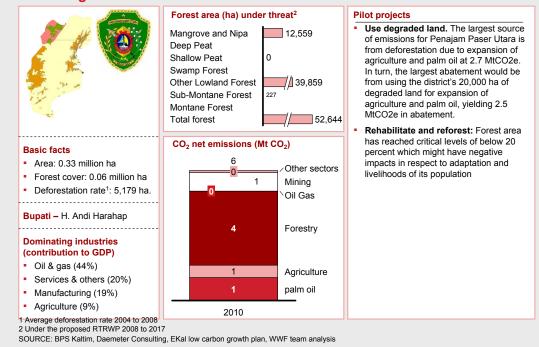

**Penajam Paser Utara (PPU)** is the smallest district in the southern part of East Kalimantan, covering an area 330,000 ha. Oil and gas make up 45 percent of the economy, but most of the population is engaged in agriculture and fishing. The district also has a significant manufacturing sector, mostly agricultural processing and industrial operations. Only 19 percent of its forest cover remains, yet forest loss continues at an annual rate of 5,000 ha. The largest driver of deforestation is the expansion of agriculture and palm oil.

The head of BLH chaired the workshop. The session was very interactive, participation from the audience was good, and a lengthy question and answer session ensued post-presentation. Although it coincided with two other big events on the same day (Hajj departure ceremony and a seminar on women's rights), attendance was excellent with over 30 participants. The audience was fairly diverse, consisting of industry participants, NGOs, academia, and a range of representatives of every government office.

PPU is adamant that emissions may likely increase if plans for building a new crude oil terminal on its shores next year are realized. Despite the negative impact on emissions from such a venture, participants cite that the terminal comes with significant social and economic benefits and therefore is not likely to face any objection from the heads of government. A middle ground solution that achieves a balance between environmental impact and such benefits will need to be found.

Exhibit 91

## Penajam Paser Utara: It is expected that PPU will loose 85 percent of it's remaining forest cover

Two large-scale rehabilitation programs are currently underway. The first is led by the government of PPU, which aims to plant over 1 million trees across the district. The second rehabilitation initiative was started by Astra plantation company, which aims to plant more than 1.4 million trees in the next few years. In spite of these two programs, the government realizes that it should not feel complacent and should commit to more low-carbon growth initiatives.

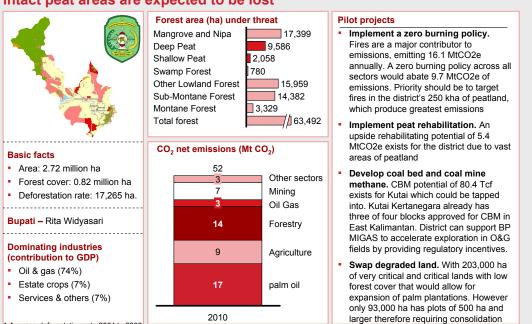

It was discussed in the workshop that PPU government's main concern is not having enough knowledge or capabilities to execute emission reduction activities. For example the head of BLH said that no matter what or how many initiatives he tries to implement in PPU, it will never be enough to fight emissions because they do not have the right experts and tools to measure the impact and to carry out the programs.

**Kutai Kartanegara** has the greatest GDP of any district at IDR 28.3 trillion in 2006 – approximately 27 percent of the total GDP for East Kalimantan. The district contains much of the upstream oil and gas fields in East Kalimantan, which account for 75 percent of district's GDP. There is substantial coal production as well, over 12M tons in 2008, the third highest in East Kalimantan. Much of Kutai Kartanegara's lowland forests have been cleared or were burnt in the massive fires in 1997 and 1998, and only 30 percent forest cover remains today. The district also contains around 250,000 ha of peatlands, the second largest of any district, but these too have been mostly deforested and drained and are in general degraded and thus a large source of ongoing emissions of more than 20 MtCO2e per year.

Chaired by the Assistant II, 33 participants attended the workshop in Kutai Kartanegara. The audience was relatively savvy in acknowledging that the drivers for climate change will inevitably change with the new possibility of carbon or REDD payments – and thus welcomed initiatives that would help them secure such new financial flows. Ideas for pilots that were raised during the discussion were implementing a zero burning policy (particularly around the 250,000 ha of remaining peatlands), reclaiming and rehabilitating mines, reforesting the Mahakan river delta

#### Kutai Kartanegara: Deforestation is expected to slow down but the last intact peat areas are expected to be lost

region, expanding oil palm plantations onto degraded land, and accelerating exploration of coal bed methane resources.

**Tarakan's** economy is built on trade and tourism. Its economy is dominated by the service sector (70 percent of GDP), which is focused on trade, hotels, and tourism. Manufacturing (11 percent of GDP) and agriculture (10 percent) are other main sectors. Tarakan has retained 20 percent of forest cover on its 25,000 ha, including mangrove forests, which are particularly important to protect the coastline from extreme weather. Tarakan is losing around 800 ha of forest a year, out of only 5,800 ha standing forest – deforestation alone drives 70 percent of its emissions. However, total emissions are relatively small compared to other districts at 1 Mt CO2e per year

The Walikota himself chaired the session of 38 participants – including participants from Pertamina and several private sector companies. The government of Tarakan is quite mature in its attitude towards climate change. One day per year is dedicated for bicycle use, and there have been several successful green projects, e.g., in land re-greening and mangrove conservation. Initiatives have also been started to study the possibility of substituting current fossil fuels for power generation with more sustainable forms, e.g., from waste. The longer term vision for Tarakan is based on future development around green manufacturing and services.

#### Districts with little or no forest cover

**Balikpapan** hosts Indonesia's second largest refinery and acts as the regional base for many of the province's oil and gas companies. Oil and gas accounts directly for 40 percent of the city's GDP, and the industry has also helped spur the growth of services. Balikpapan's emissions profile resembles much more that of the industrialized world than the rest of East Kalimantan. Manufacturing and services account for a sizeable share, mainly driven by consumption of power and transport by the city's residents and businesses. The refining process alone is estimated to produce 3.3 MtCO2e from the energy consumed as well as emissions produced by flaring and other processes. Only 540 ha of forest is deforested a year.

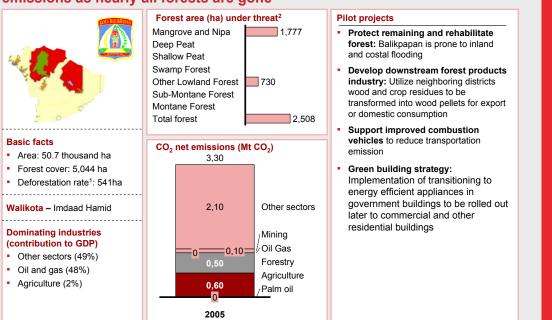

Within the last decade, Balikpapan has taken a conscious decision to inhibit the proliferation of mines within the city due to the risks that such mines pose to a clean water supply. Furthermore, the city has created a Rencana Aksi Mitigasi & Adaptasi Perubahan Iklim, a blueprint towards creating a city that develops sustainably. An example of this expressed during the workshop is that many disagreed with the plans to create the Pulau Balang bridge, citing environmental concerns around construction plans that were non-friendly to environmental and biodiversity issues and the high possibility for heightened emissions from diverting traffic a longer distance.

**Samarinda.** As the capital city of the province, two-thirds of its USD 1.1 billion economy is from services, mainly public administration. While the city has no palm oil or forest plantations, it does contain coal deposits, the mining of which generates 4 percent of GDP. As the city comprises only 72,000 ha and is already mostly deforested, there are few emissions from changes in land use. However, Samarinda does have small amounts of peat, around 20,000 ha, which are degraded and decomposing, releasing an estimated 1.7 MtCO2e annually. Most of the city's emissions are due to the power and transportation needs of its manufacturing and service sectors, which combined produce 2 MtCO2e annually.

The Assistant IV chaired the session of 15 participants. The presentation focused on non-LULUCF sectors – power generation and transportation – which went a long way to engage the audience in a thorough and meaningful discussion on potential abatement initiatives. A representative of the local Bappeda highlighted the need for a green-centric spatial plan that was more in line with abatement and re-greening initiatives as well as the need to revise the current spatial plan process at the provincial level to become more transparent to the public and district alike. There currently are firm plans towards bringing forest cover up beyond the current level of less than 5 percent today.

#### Balikpapan: The emissions profile is dominated by non land use related emissions as nearly all forests are gone

Bontang. The Bontang LNG plant is the largest in Indonesia and provides 90 percent of the city's GDP. The plant is operated by PT Badak; another company, PT Pupuk Kaltim produces ammonia and fertilizer using natural gas feed from the plant. Due to declining production from nearby gas fields, the LNG plant capacity has declined to 80 percent today and is projected to decline further as the Makaham field moves off-plateau.<sup>40</sup> Today, oil and gas accounts for 18.5 MtCO2e in annual emissions; with only 3,000 ha of standing forest, emissions from land use changes, power, or transport are low in comparison.

#### Exhibit 96

#### Bontang: Bontang's economy is completely depending on its LNG plant

The workshop was preceded by a morning meeting with the District Sekda, who unfortunately could not attend the session later in the afternoon. Instead the Assistant II chaired the session of 20 participants. The city government sees a green development as very important to attract investors and therefore has gone some way towards incorporating low carbon elements into the regulatory framework – for example, creating a Renstra<sup>41</sup> "Sustainable Bontang 2010". There are some early low carbon development initiatives already taking shape on the ground in Bontang, namely using waste for biomass under a collaboration with GTZ, and several clean development mechanism (CDM) proposals from PT Badak to improve yield from current gas fields that feed into the Bontang LNG trains. Unfortunately, to date none of the initiatives have yet succeeded in obtaining carbon payments.

<sup>40</sup> Refers to the portion of production from an oil or gas field when production is at peak capacity, after which it will begin to reduce over time as the reserve depletes

<sup>41</sup> Renstra: Rencana Strategi, or Strategic Plan

#### Additional discussion and closing

The roadshows highlight several important features of the existing state of affairs across East Kalimantan province. For one, there are large differences in starting positions of each of the districts, with a number exhibiting a major proportion of emissions from deforestation and forest and peat degradation (high forest cover districts), whilst others, the cities in particular, the oil and gas, transport and power generation sectors dominate emissions. The implication for us is that broad-brush initiatives in any one specific sector cannot be applied homogenously across the province. Instead, a mix of relevant initiatives is needed to fully account for differences among district starting points.

Secondly, **there is a need for reinforced institutional capacity at the provincial level** to better support districts in adapting low carbon development initiatives, particularly to resolve regulatory issues and act as coordinator for multiple initiatives at the district level. Such an entity could also act to disseminate and cross-fertilize information between central government and amongst districts and help to ensure each district is aligned towards supporting a provincial level emission reduction target. Tangibly, this entity could be a permanent unit housed within the Governor's office, much like the National Council on Climate Change (Dewan Nasional Perubahan Iklim, DNPI), which is at the provincial level.

Thirdly, **there is a need to improve general awareness of the public to the issue of climate change,** and more specifically the intentions of the national government to adopt a REDD strategy. The province needs to move fast to communicate the implications of such a strategy to the districts and begin early preparations to face the changes ahead.

Lastly, **there is a need to increase the urgency of starting implementation of low carbon initiatives at the district level.** From conversations with district participants it appears there is a clear disconnect between the 2020 emission reduction target of 26 percent made public by President Yudhoyono with on-the-ground initiatives at the district level to support and realize this reduction. In general, districts find it difficult to translate the concept of a high-level emission target with, for example, land use change decisions, enforcement procedures and mechanisms, policy and regulatory changes, compensation schemes for avoided deforestation, and other such examples. Our role is therefore invaluable to articulate such requirements to district level authorities via guidelines, procedures, and other supporting activities. What should also be emphasized is two evolving thematic trends that link Indonesia to the global landscape: 1) there is now a clearer possibility of carbon payments to remunerate or compensate emission reduction initiatives and 2) Indonesia is in a very competitive position to secure the earliest emission abatement credits due to ample opportunity and likely low price of abatement in comparison with more developed countries in the world.

#### Next steps

As a follow-up to each roadshow, district participants were asked to submit more detailed proposals of two to five pilot ideas to the team within a period of two weeks from the workshop date. These proposals were to be submitted on behalf of the district as a whole, and therefore, participants were advised to reconvene key stakeholders in a separate session following the roadshow to deliberate on potential ideas and prioritize what the eventual proposal submitted.

The pilot proposals have given the provincial government a clearer insight of the richness of ideas and plans at the ground level within each district. At the same time, it is also our intention to analyze the submitted proposals in more detail to prioritize them based on emission reduction potential, economic development impact, ease of implementation, and implementation cost. The intention is to turn these proposals into potential projects that the provincial government can support in line with the implementation phase of the low carbon economic development strategy.

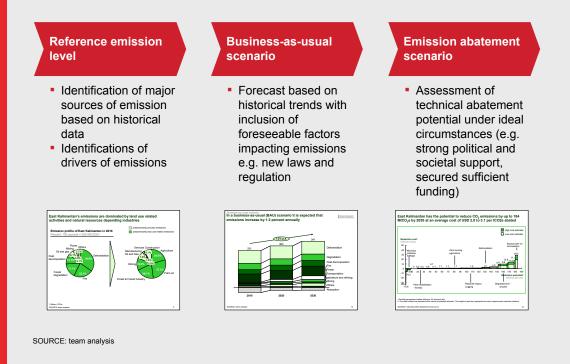

## **EMISSION CALCULATION**

East Kalimantan's greenhouse gas (GHG) emissions and abatement potential was calculated by following a three-step approach (Exhibit 97): 1) setting the reference level, 2) developing a business-as-usual scenario, and 3) by calculating the abatement potential. Sources of emissions included in the analysis stem from deforestation, forest degradation, peat decomposition, and vegetation fire; process emissions from agriculture, mining, oil and gas, power, and cement; and emissions from transportation and buildings.

To address emissions abatement in a more efficient manner, sources of emissions, such as deforestation, have been split and allocated to specific industrial activities, such as the palm oil industry.

#### Exhibit 97

#### The applied methodology is following a three step approach

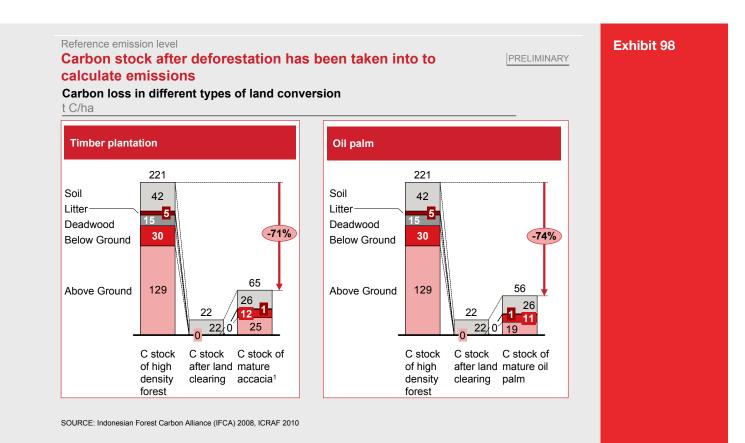

#### **Reference level emission scenario**

Land use related emissions dominate East Kalimantan's emissions profile. This chapter therefore focuses on providing clarity on the estimates of emissions and abatement from land use sectors.

The reference level for emissions from deforestation is based on historical annual deforestation rates multiplied by a default value for carbon loss. In the case of East Kalimantan, three<sup>42</sup> deforestation rates ranging from 37,000 ha to 248,000 ha per year published by different sources were considered. After consulting key stakeholders it was agreed to use the annual historical deforestation rate of 151,268 ha published by WWF Indonesia. For gross carbon loss, a default value of 221 t C per ha was applied.<sup>43</sup> Based on IPCC's recommended process for calculating

<sup>42</sup> Ministry of Forestry 2009, WWF Indonesia 2009, IFCA 2008

<sup>43</sup> IFCA 2008

emissions from land use, land use change, and forestry (LULUCF) absorption and carbon stock from managed forests as well as other land uses which meet FAO forest definiton, e.g., oil palm plantations, were taken into account (Exhibit 98). In consequence, all emissions reported throughout the document are net emissions.

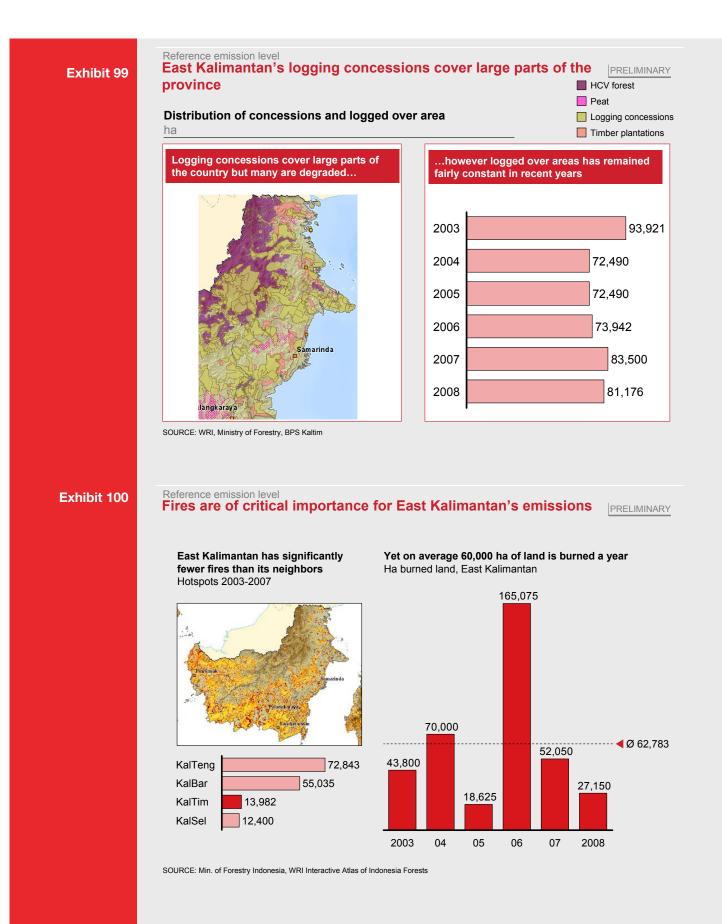

To allocate emissions from deforestation and forest degradation to specific industries, the expansion<sup>44</sup> of these industries into forested areas between 2003 and 2006 was applied.

Emissions for forest degradation were calculated by multiplying the logged over area (Exhibit 99) with a default value of net carbon loss from non-sustainable logging practices.

Emissions from fires were calculated depending on their location, however the basis was the number of hotspots published in the Ministry of Forestry 2008 statistics, and the location was determined by using the hotspot distribution map developed by WRI in cooperation with the Ministry of Forestry in 2008 (Exhibit 100). The average size of a hotspot was assumed to be 25 ha based on expert interviews; however there are uncertainties around the average size of a hotspot as there are large differences from year to year depending on the climate in this year. This is especially true within peatland as they often burn below the surface. In case of fires on mineral soils an average carbon loss of 27 percent (60 t C per ha) of the initial carbon stock was applied. In case of fires on peatland a carbon loss of 90 percent (200 t C per ha) of the initial carbon stock was assumed.

Emissions from peatland are derived from the physical status of East Kalimantan's peatland. It is assumed that primary peat is not emitting carbon, while secondary forests and especially converted peatlands are emitting up to 60 t CO2e per ha per year. The primary data source to identify the area of degraded peatland data was the Ministry of Forestry. As primary research on gas exchange was not possible, emissions from peatland decomposition were derived from

<sup>44</sup> Ministry of Forestry – Rekalkulasi Penutupan Lahan Indonesia (Tahun 2008), BPS Kalimantan Timur 2010

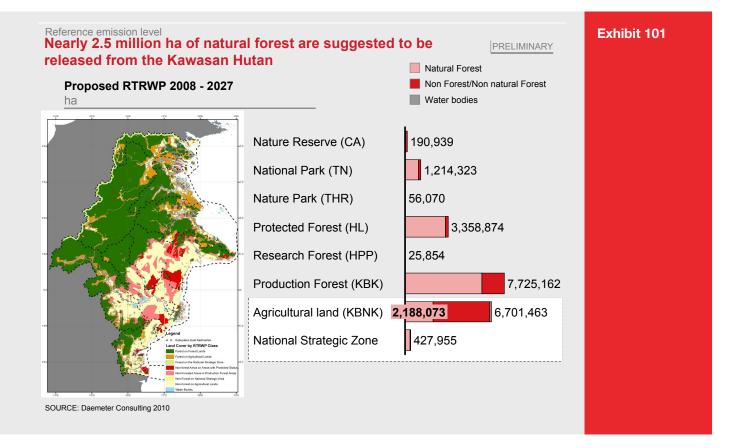

Indonesia's total peatland decomposition emissions based on East Kalimantan's percentage share of degraded peatland.

Emissions from other sources, e.g., industrial processes or transportation, were derived from national data sources.<sup>45</sup> East Kalimantan's percentage share was calculated by using publicly available data, e.g., GDP, population, as denominators as more detailed data, e.g., vehicle types or specific data on industrial production, was not available.

## **Business-as-usual (BAU) scenario**

The BAU scenario describes a future emissions scenario without any future political intervention, e.g., a rezoning of the Kawasan Hutan. It is also based on the assumption that carbon payments will only be made through the already existing voluntary carbon market schemes and not through a multinational compliance market.

The deforestation BAU scenario is based on the initially proposed spatial plan RTRWP covering the time period from 2010 to 2030. Based on maps and satellite interpretation, approximately 2.5 million ha are under threat of being converted to other land use with the majority located in the northern parts of East Kalimantan (Exhibit 101).

Three major drivers were identified for future conversion of natural forest based on spatial analysis of the existing location licenses. The largest driver of deforestation is expected to be the expansion of oil palm plantations, with more than 1 million ha of Izin Lokasi already issued for areas currently covered with forests. Second to oil palm is the expansion of timber plantations, with more than 600,000 ha of not yet developed licenses for natural forest locations. While the establishment of oil

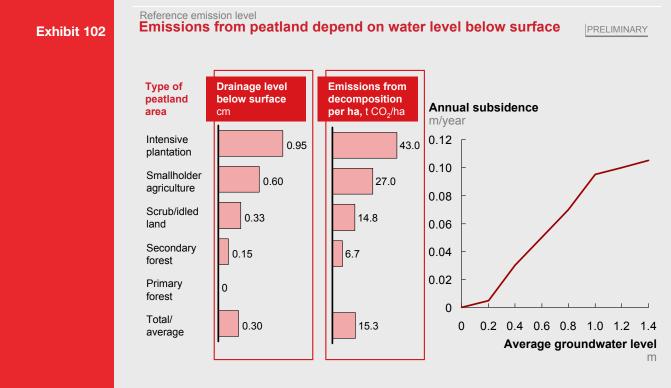

<sup>45</sup> DNPI (2010) - Indonesia Greenhouse Gas Abatement Cost Curve

palm does not result in deforestation,<sup>46</sup> as plantations meet official Indonesian forest definitions, it does result in significant carbon losses of up to 70 percent compared with natural forests. The third largest driver of deforestation is mining. While the overall forested area covered with mining licenses actually exceeds the area of oil palm by approximately 300,000 ha, it is expected that only 15 to 20 percent of the total area will actually be deforested. Other drivers for deforestation are infrastructural development of roads and settlements as well as agriculture.

Future emissions from vegetation fires are difficult to estimate as there are large differences between years depending on the climate, and the fires are linked to land conversion. As there is no indication of a strong enforcement of zero burning at this stage, it is assumed that under the BAU scenario emissions from fires will remain constant going forward.

Peat emissions are expected to increase as more peatland will be converted under the BAU scenario as indicated through the new spatial plan. Emission levels for different land types are presented in Exhibit 102. Under the BAU scenario it is assumed that emissions increase in line with the area of converted peatland. Under the current proposed spatial plan approximately 200,000 ha of peatlands are designated for conversion.

Emissions not related to land use change are expected to increase in line with future GDP and population growth and are derived from Indonesia's national BAU scenario.

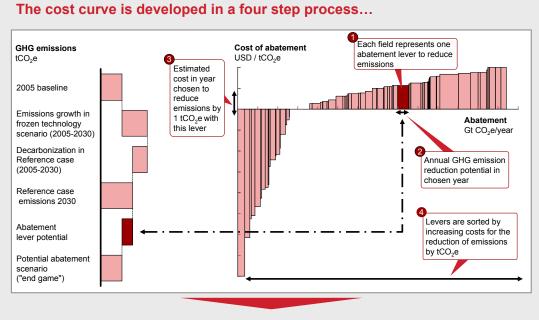

SOURCE: Hooijer et al 2009, Couwenberg et al. 2009

<sup>46</sup> Indonesia defines forest as wood vegetation covering an area greater than 0.25 ha with a potential to reach a minimum vegetation height of 5m and a crown cover of 30 percent.

## Abatement potential and cost

Abatement potential and its respective costs are shown in the form of a cost curve. The cost curve shows the range of emission reduction actions that are technically feasible already today or are highly likely to be available by 2030.

The width of each bar represents the potential of that opportunity to reduce GHG emissions in a specific year compared to a BAU scenario. The potential of each opportunity assumes aggressive implementation starting in 2010 to capture that specific opportunity and so does not represent a forecast of how each opportunity will develop. The height of each bar represents the average cost of avoiding 1 ton of CO2e by 2030 through that opportunity. The cost is a weighted average across sub-opportunities and years. All costs are in 2005 real USD. From left to right, the graph presents the lowest-cost abatement opportunities to the highest-cost<sup>47</sup> (Exhibit 103). The uncertainty of volume and cost estimates can be significant for individual opportunities, in particular for LULUCF and peat, and for emerging technologies within the oil and gas and the mining sectors.

 The cost curve displays abatement potential, and corresponding cost, for each abatement lever relative to a "business-as-usual" scenario

The merit order is applied based on the cheapest measures in 2030 in USD/tCO<sub>2</sub>e

Source: McKinsey & Company Global GHG Abatement Cost Curve v2.0

The GHG cost curve aims to look at emission reduction opportunities with one consistent methodology, rather than to analyze in detail any individual emission reduction opportunity. Therefore the curve should be used for overall comparisons of the size and cost of different opportunities, the relative importance of different sectors, and the overall size of the emission reduction opportunity. It can also be used as a simulation tool for testing different implementation scenarios, energy prices, interest rates, and technological developments.

#### Exhibit 103

<sup>47</sup> A negative cost lever on the cost curve implies that while an upfront capital investment may be required, the lever will more than pay for itself over its lifetime through energy savings when the investment is evaluated at a societal cost of capital (i.e., for the purposes of this study, this has been taken at 4 percent).

The cost of abatement is calculated from a societal perspective (i.e., excluding taxes, subsidies, and with a capital cost similar to government bond rates), which is useful to allow comparisons of opportunities and costs across countries, sectors, and individual opportunities. However it also means that the costs calculated are different from the costs a company or consumer would see, as taxes, subsidies, and different interest rates would be included in their calculations. Therefore the curve cannot be used for determining switching economics between investments, nor for forecasting CO2 prices. The cost of each opportunity also does not fully include transaction and program costs to implement the opportunity on a large scale, as these are highly dependent on how policy makers choose to implement each opportunity, e.g., policy makers can choose if they want to tackle a specific abatement opportunity technically or through a set of new regulations and enforcement. The costs to fully implement specific reduction opportunities, therefore, will in most cases be higher than those shown in the cost curve.

## ECONOMIC DEVELOPMENT OPPORTUNITIES

The economic model is developed by forecasting the 5 largest individual economic sectors Forestry, Estate crops, Agriculture, Mining and Oil and Gas. For each sector a base case scenario and one green growth scenario was developed.

#### **Base case scenario**

The forecast for each sector is based primarily on the historical growth rate of the sector in the province. Where growth is judged to be unsustainably high (e.g., greater than 10 percent real per annum growth), a transition to the historical growth rate of the sector at the national level is assumed. An overview of historical growth rates of each sector is provided in Table 6.

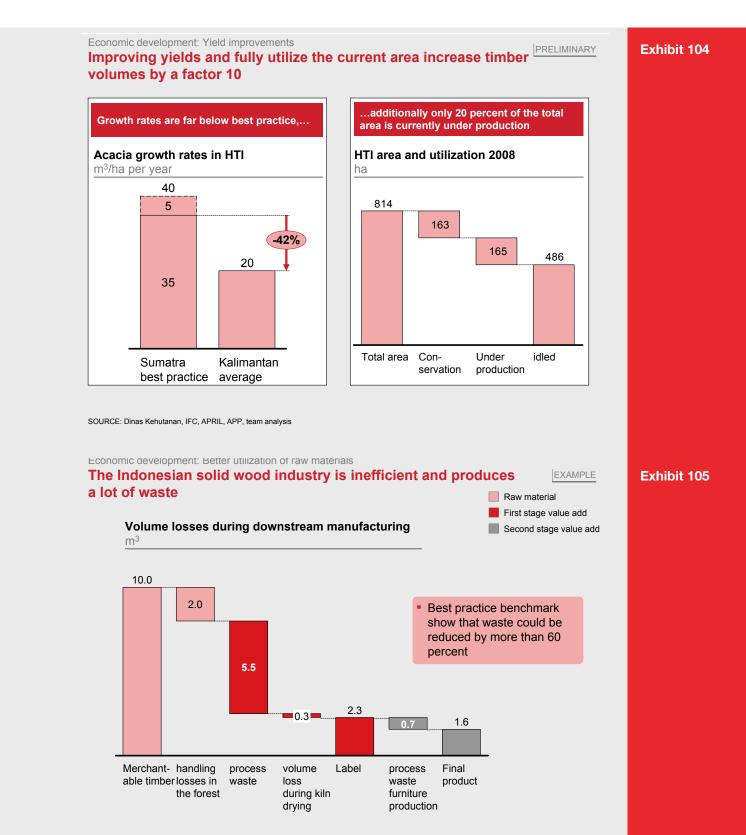

## **Green growth scenario**

The green growth scenario is based on the assumption that a general shift of East Kalimantan's economy to a a low emission pathway is pursued. One critical assumption is that REDD payments will be available to cover the societal gap which could occur from not developing certain business as usual economic activites.

### **Forestry sector**

Economic development opportunities within this sector are based on 3 underlying assumptions:

- Decrease waste in natural logging: Under current practices only minor parts of a felled tree are utilized (Exhibit 32). Full tree utilization could increase revenues through additional timber sales to pulp mills or bioenergy production sites for a specific tree by more than 50 percent (Exhibit 104). Large amounts of waste are produced along the value chain through non-optimal bucking of logs and process losses in the saw mills as a result of inapprobriate technology applications. Compare with best practices yields through optimal utilization of timber can be increased threefold (Exhibit 105)
- Increase productivity of timber plantations: East Kalimantan's timber plantations is 40 percent lower than best practice plantations in Sumatra. Furthermore only 165,000 ha of a total of 810,000 ha are actually under production. Reaching bestpractice benchmark and bringing the maximum area under production could yield in an annual harvest of 28 million m3 pulpwood and revenues of USD 850 million under current market prices og USD 60 per tonne and increase GDP contribution from timber plantations to IDR 4.8 trillion in 2030

SOURCE: Putz et al 2010, team analysis

#### Exhibit 106

#### A green field pulp mill would generate up to 1.2 billion USD revenues

#### State of the art green field kraft pulp mill:

- Export to China 1 1.5 million tonnes capacity/yr hardwood kraft pulp mill 160,000 - 240,00 ha pulpwood plantation afforested on
- bare land Capex
  - 1 1.5 billion USD for mill
  - 200 300 million USD for pulpwood plantation leases and establishment
- Planning, construction and plantation establishment time 4 6 years
- Ramp up 6 month to 1 year

#### Key data points:

- 400 1,200 million USD revenues<sup>3</sup>
- ~300 600 million USD total cash costs
- ~4 6 million m<sup>3</sup> pulpwood per year
- ~15 30 million tonnes CO2 average inventory in pulpwood plantation1,2

1 Assuming 6 year rotation length, 25m<sup>3</sup>/ha/yr yield 2 Could be increased substantially by planting on drained peat land, if water level is raised again to the maximum level still tolerable for trees; raising again the water level by each meter would avoid 50,000 tonnes of CO<sup>2</sup> emissions 3 10 year price range, excluding recent price peaks due to earth quake in Chile, etc.

SOURCE: ÅF, RISI, Cornerstone, Expert knowledge, McKinsey Analysis, company websites

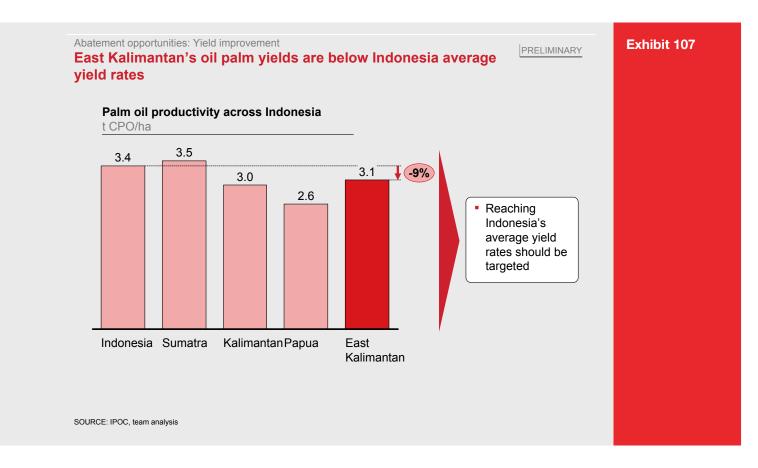

Downstream pulp and paper: Assuming that production in East Kalimantan's timber plantations can reach above described timber production levels downstream developments can be pursued. Assuming two additional pulp mills together with the already existing pulp mill in Berau could increase GDP contribution above business-as-usual from IDR 1.8 trillion to more than IDR 10 trillion.

## **Estate crops**

Analysis for estate crops is focusing on palm oil as other estate crops as rubber haven't shown the massive expansion like oil palm in recent years and is also not expected to do so under current market prieces and the significantly higer net present value from palm oil.

Under the business-as-usual scenario it is expected that the area under oil palm production will increase from app. 450,000 ha to 1,250,000 ha. The expected expansion is based on the province's economic development plan. It is furthermore exoected that growth rates will only marginal increase compared with current yield rates of 3.1 t CPO per ha annually (Exhibit 107).

Under the green growth scenario it is assumed that the expansion will be limited to degraded land suitable for oil palm (550,000 ha) within KBNK. The total area planted in 2030 will therefore only reach 1,050,000 ha under the green growth scenario. Without additional productivity improvements this scenario would result in GDP losses of 10 percent compared to business-asusual. However it is assumed that East Kalimantan will reach average Indonesian productivity levels in the future, which would than result in growth rates of 3.4 t CPO per year and although planted in a smaller area would result in the same overall CPO production than in the business as usual scenario.

Additional revenues could come through REDD payments through the use of degraded land and the resulting avoided deforestation. Assuming carbon payments of IDR 55,000 per tCO2e could result in a GDP contribution of IDR 1.4 trillion in 2030. Job creation within the oil palm sector is purely linked to area expansion. Based on Indonesian benchmarks approximately 1 worker can handle 7 ha. As the area expansion in the green growth scenarion is slightly smaller than under the business-as-usual scenario the number of jobs created might be slightly lower.

#### Agriculture

Economic development activities within the agriculture sector are purely related to productivity improvements. East Kalimantan is showing below average growth rates for all major crops including rice, cassava, maize and potatoes (Exhibit 40). Going forward it is assumed that East Kalimantan will be able to reach average Indonesian production levels which will lift GDP by more than IDR 3 trillion compared to the business-as-usual scenario (Exhibit 41).
